# GTODAY MY BANK IS NO 199

"It came as no surprise to see KVB being ranked No.1\* among Private Sector Banks. With its wide range of schemes - something for everyone and its quality of customer service, it was bound to happen. Sooner or later.

In fact for me KVB is much more than a bank. It's family. And I guess if that's how it is with me, that's how it must be for it's entire clientele. No wonder it's first among Private Sector Banks and No.3 among Indian Scheduled Commercial Banks. I'd like to say 'Thanks KVB' for the privilege of banking with the best bank. And thanks for always treating me like your No.1 customer."

#### Sexual Violence, Discursive Formations and the State

#### Veena Das

While in the face of the disorder of collective violence the state seems to absent itself so that we cannot guess how the judicial discourse would have constructed pathological sexuality, we have evidence of how 'individual pathology' is constructed in the rape trial during normal periods. Further, in the dense discursivity of the state as it engages in separating the normal from the pathological, we get a production of bodies (male and female) that normalises sexual violence at least for the purpose of the law.

THE World Mental Health Report contends that domestic violence and rape constitute approximately 5 per cent of the global health burden for women in their reproductive years. Realising the enormity of the health burden on women that this imposes, the report urges the international community to take the physical and sexual abuse of women as an area of priority for research and social action. This paper looks at the processes through which, I believe, sexual and physical violence through the mechanism of rape is 'normalised' in Indian society. It also suggests certain directions in which the rape law might move to provide better protection to women.

Sexual violence against women is constitutive of social and political disorder in India. Widespread violence against women was witnessed at the time of the Partition of India with more than hundred thousand women having been abducted from each of the two parts of the Punjab alone [Butalia 1993; Menon and Bhasin 1993]. Not only were women abducted and raped, but slogans like 'Victory to India' and 'Long Live Pakistan' were said to have been painfully inscribed on the private parts of women. Although a Fact Finding Organisation was set up to enquire into these atrocities, the findings of the organisation were never made public. I have argued elsewhere that the bodies of women became political signs, territories on which the political programmes of the rioting communities of men were inscribed [Das 1995]. Although the judicial silence of this occasion is a stunning fact of history, I think one can suggest that in order to read this silence it is necessary to juxtapose it with other occasions when the judicial discourse is engaged in the task of separating 'normal' sexuality from 'pathological' sexuality, and to ask whether the very logic by which courts of law in India bring out this separation does not 'normalise' the violence against women during periods of disorder. In other words I submit that while in the face of the disorder of collective violence the state seems to absent itself so that we cannot guess how the judicial discourse would have constructed pathological sexuality, we do have evidence of how, 'individual pathology' is constructed in the rape trial during normal periods; and further, that in the dense discursivity of the state as it engages in separating the normal from the pathological, we get a production of bodies (male and female) that normalises sexual violence at least for purposes of the law.

#### RAPE IN JUDICIAL DISCOURSE

The pervasiveness of sexual violence at every level of social organisation has been decisively demonstrated by feminist scholars. Many have claimed that the everyday heterosexual practices and the practice of rape participate in the same structure of relations defined by patriarchal ideologies. For example MacKinnon has argued that "... sexuality is a set of practices that inscribes gender as unequal in social life. On this level sexual abuse and its frequency reveal and participate in a common structural reality with everyday sexual practice" [MacKinnon 1992: 126; see also MacKinnon 1989]. But there is a peculiar puzzle here. If sexuality in everyday life, sexual ecstasy and sexual abuse have complex, albeit discontinuous linkages, then how is it that the state steps in through its judicial institutions to 'problematise' the assumptions of everyday life regarding men's uncontested rights over women's bodies? If the law was only interested in treating sexual offences on analogy with offences against male property, as many have alleged, it would be difficult to explain the importance of the notion of consent in the case law as it has developed in India and elsewhere. Indeed, 'consent' of the woman turns out to be the most significant category for distinguishing between nonpunishable sexual commerce with a woman and the offence of rape against her. In this context Smart (1989) considers that the significance of the category of consent is that it helps to systematically transform rape into consensual sex in the legal system. More recently Matoesian (1993) has identified court room talk as the site for examining how the victim's experience of sexual violence is delegitimised and decriminalised by converting it into consensual sex. "Courtroom talk captures the moment to moment enactment and reproduction of rape as criminal social fact" [Matoesian 1993:27].

There is a genealogical link between the argument made here and Foucault's understanding of the relation between power and sex. In his history of sexuality Foucault (1980) understood by power as essentially that which seeks to dictate its law to sex. This means first of all that sex is placed by power in a binary system of licit versus illicit and permitted versus forbidden sex. In this reading the effects of power take the general form of limit and lack. Yet it is Foucault above any other thinker who has emphasised that sexuality in modern societies is not so much a product of judiciopolitical prohibitions as of the will to knowledge/power that lies behind discourses defined by techniques of confession and scientific discursivity. Hence, "we must not think that by saying yes to sex, one says no to power" [Foucault 1980: 157]. This seems to imply that the search for freedom in the pleasures of sex is ironically what places a person under the domain of power. The distinction between sexual pleasure and sexual subjugation becomes blurred here. It is this very play between pleasure and subjugation, I shall argue, that defines techniques of confession in judicio-political discourse so that the woman's body is made to confess against her explicit speech; subjugation is read as pleasure. The court room trial and the structure of sentencing demonstrate how a woman's no to sex can be converted into a yes to it through the operation of judicial grammar and judicial sentencing. It is in these practices that we shall see what consent means in the dense discursivity of a field defined by the juridical

#### JUDICIAL DISCOURSE

One way of conceptualising judicial discourse is to see it as a cross roads for multiple transactions by which a particular way of talking about rape sorts women into categories that brings law and social practices into congruence with each other. In their pathbreaking work on a semiotic under-

standing of judicial discourse, Greimas and Landowski (1976) have described how the legislative function of this discourse first separates the licit and illicit comportment of human desires through normative enunciations. These desires, they argued, are then classified and hierarchised through processes of judicial verification by an application of such distinctions as nature and culture on the one hand, and individual and social, on the other.

The legislative function in the discourse is a function of enunciation – it belongs to the order of being by which legal objects are brought into existence in the process of being named. The adjudicatory level, on the other hand, belongs to the order of doing. Although the linguistic practices encountered in judicial prose orient one towards thinking that the processes of adjudication belong to a reality that exists prior to being named, in fact it is the legislative function that gives direction to those elements of the world that will be selected for reference. Thus the order of doing is the operational sphere of those semiotic objects which have already been brought into existence by legislative enunciations or by the legislative definitions of reality.

The juridical domain is defined by the combinations of prescriptions and interdictions, 'that create a solid and immobile architecture', but since the production of rules is constantly subject to verification, the undifferentiated domains of non-prescriptions and non-interdictions that initially define the non-juridical domain can move into the juridical domain through the application of juridical phrases. In the final analysis, then, the juridical discourse splits into the two poles of grammar and semanticity. The legislative level is the level of grammar without content while the adjudicatory processes relate to the level of judicial verification through which content is given to the judicial grammar. The level of non-judicial discourse - devoid of both judicial grammar and judicial semanticity constitutes a virtual world elements of which may enter the judicial world through judicial production and verification. It is this double process of judicial production and verification that negotiates the 'reality' of societal categories and fits it into frames of law. In the process the judicial discourse comes to mediate the everyday categories of sexuality and sexual violence, sorting and classifying the normal and the pathological in terms of marriage and alliance. It is because of the manner in which categories of alliance are brought into the process of judicial verification, separating women into 'consenting' and 'non-consenting' ones; regulating male desire by channelising it towards women of appropriate categories -

that we can see why judicial discourse becomes silent when rules of alliance stand suspended during periods of collective violence. Let me try to give flesh to this argument by a consideration of the rape law in India.

#### RAPE IN INDIAN CASE LAW

At the level of the codification of law, rape constitutes an offence against the body. At one level, it may be seen along with other crimes in which force is used against a person resulting in grievous harm or death of the victim. Yet by separating and codifying a separate category under the heading of sexual offences, the Indian Penal Code, directly recognises the right of the state to regulate sexuality. It is important therefore to note that although in the sentencing structures one finds that the judges are compelled to constantly distinguish between grievous bodily harm caused by an attempt to rape a woman and rape proper; in the penal code itself sexual offences are classified through a binary distinction between 'rape' and 'unnatural offences'. The deployment of the concept of nature, as we shall see later, allows rape to be viewed as an offence which is 'natural' and men as falling into a natural state when the ordering mechanisms of culture are absent.

The law relating to crimes in India was codified in 1860 by the colonial British government by the introduction of the Indian Penal Code [Dhagamwar 1992]. The Code identified rape as an offence and made it punishable under Section 376. The definition of rape in this section read as follows:

A man is said to commit 'rape' who, except in the cases hereafter excepted, has sexual intercourse with a woman under circumstances falling under any of the five following descriptions:

First - against her will.

Secondly - without her consent.

Thirdly - with her consent, when her consent has been obtained by putting her in fear of death or of hurt.

Fourthly – With her consent when the man knows that he is not her husband, and that her consent is given because she believes that he is another man to whom she is or believes herself to be lawfully married Fifthly – with or without her consent, when she is under 10 years of age.

Explanation – Penetration is sufficient to constitut, the sexual intercourse necessary to the offence of rape.

Sexual intercourse by a man with his own wife, the wife not being under 10 years of age is not rape.

The original age of 10 years in the fifth clause has been amended through a series of legislative amendments so that it now stands at 16 years.

 Even a cursory reading of the text would make it clear that in defining the offence of rape, the concern is with regulation of sexuality rather than protection of body integrity of the woman. One of the commentators to this paper, Stacy Cherry (1994), raised the question that a woman giving her consent because she believes herself to be lawfully married to an 'alleged rapist' seems particularly problematic. What kind of circumstances must exist, asked Cherry, for a woman to believe that she is married and yet possibly not be married? To my mind, this clause clearly brings out the manner in which social reality is mediated through the judicial discourse. For instance, in cases of bigamy a woman may believe herself to be married but the marriage is null and void in law. Hence although the husband may not have used any force in having sexual relations with her and indeed, the woman may have consented to the sexual relationship, in law he would be defined as a rapist according to this clause. When we read this along with the clause which does not consider it judicially possible for a husband to 'rape' his wife if she is above the age of 16, we can see that the offence of rape is about the regulation of sexuality and not about the protection of the body integrity of women. An examination of the case law shows that the consent of a woman can be read as nonconsent, and the absence of consent can be read as consent, depending upon where she stands in the system of alliance. What rape as illegal sexual commerce offends, it seems, is not the body of the woman but the order of correct sexual relations as defined by societal norms.

It is not that the law is not concerned with the question of consent. At the level of judicial verification, the question of mury to the body becomes crucial in finding evidence of consent, but at the level of judicial enunciation of norms that the question of consent in the definition of rape is a very complicated issue indeed. This becomes even more clear if we see the subsequent Section 377, which defines 'unnatural offences' and prescribes punishment for these.

Section 377 reads as follows: "Whoever voluntarily has carnal intercourse against the order of nature with any man, woman or animal, shall be punished with imprisonment of life, or with imprisonment of either description for a term which may extend to 10 years and shall also be hable to fine." The explanation states that "Penetration is sufficient to constitute the carnal intercourse necessary to the offence described in this section" while a Comment to the Section clarifies that this particular offence consists of carnal knowledge against the order of nature.

about the case law utal developed around the category of unnatural offences at the moment, but an examination of this seems important to further amplify the notions of 'nature' as deployed in the judicial discourse. For the present I shall be content to note that in contrast to the law on rape, in which the notion of consent plays a very important part, the idea of voluntary participation is crucial for defining offences 'against the order of nature'. Thus, in law, a man cannot be raped by definition and a woman submitted to sado-masochist practices by a man through the use of force could not be said to be raped. one is then compelled to conclude that rape is not an unnatural act. Indeed, as Charles Bright (1994) stated succinctly in his comments on this paper, "the whole question of female consent becomes a process of positioning the male to do what comes naturally - that is to act from and in nature, in full accord with both body (desire) and speech (will)". I think the point is sufficiently clear that the rape law is not oriented towards protecting the body integrity of a woman but towards the regulation of sexuality and that the category of nature is deployed as an important category for effecting this

Important amendments to the rape law have taken place in recent years (see Agnes 1992). One must treat 1979 as a crucial year when serious gaps were identified in the law and a push towards reform was initiated. The precipitating event was, as is well known, the Supreme Court judgment in the case of Tukaram versus State of Maharashtra, AIR 1979, SC 185. The facts of the case were hat a young girl Mathura was summoned to the police station on a complaint of abduction lodged by her brother against her lover. She came to the police station along with her relatives, including her brother. She alleged that while the relatives were asked to wait, she was taken to the rear of the main building where the head constable raped her while a second constable made an attempt to rape her. The accused were acquitted by the Sessions Court who found no evidence of force having been used. The High Court, on appeal, reversed the finding of the Sessions Court on the grounds that it had failed to distinguish between 'consent' and 'passive submission'. The Supreme Court in appeal held that since the victim had not raised any alarm, her allegations were untrue. In the course of pronouncing the judgments, several statements were made in the respective courts regarding the girl in which she was described is a 'shocking liar' and frequent references of her having been habituated to sex weighed leavily with the Supreme Court in discrediting her own account of the event. This judgment was strongly protested by and Sarkar 1979). It was their agonised formulations that led to a countrywide mobilisation of women's groups to press for changes in rape law. After discussions in parliament and the submissions of the Law Commission on this question, the rape law was amended both with regard to procedural and substantive issues in 1983. In the amended law, efforts were made to tighten the law in favour of the victim. More specifically, the category of custodial rape was defined. The burden of proof was shifted to the accused in the case of custodial rape and a minimum punishment of 10 years rigorous imprisonment was prescribed. Under this provision, gang tape, and rape with a woman known to be pregnant would also normally lead to a minimum 10 years maprisonment [Dhagmwar 1994].

The 1983 amendment cited more than 100 cases to clarify the different clauses. A compilation of these cases, undertaken by Pratiksha Baxi,' shows that there are two major concerns in the case law- one pertains to the definition of consent and the second to the judicial definition of what constitutes 'penetration'.

As far as consent is concerned, the case law evolves in the direction that consent cannot be obtained after the act, that a woman who is sleeping or is intoxicated cannot give consent; that a woman who is not of sound mind cannot give consent; that if she had a misapprehension of the act then she cannot be said to have given consent. It seems from these cases that consent is defined in the process of judicial verification as an act of reason and will. This is clearly spelt out in Idan Singh 1977 Cri LJ 556 (Raj) in which if was stated that consent was an act of reason in which there was a conscious and voluntary acceptance of the act of sexual intercourse Yet there is a counter text which assumes consent to be not only a matter of cognitive and moral recognition, but also the choice a woman makes between resistance and assent (Rao Harnaram Singh (1958) Cr LJ 563). Here we see that the will of the woman as expressed in her speech and the body of the woman as providing evidence of acceptance or rejection, are set in opposition to each other. As we shall see later, the body is made to often speak as under torture, against the idea of consent as constituting a cognitive category. Finally, since the underlying idea is that sexual intercourse with a woman defined as vaginal penetration is an act of nature, it is rarely asked as to what is constitutive of the act of sexual intercourse that a woman is consenting to? For example, in Jarnail Singh 1972 Cri LJ 824 (Raj), it was stated that if consent is given prior to sexual intercourse no matter how tardily or reluctantly and no matter

not amount to rape. In all these issues a way of reading the relation between signs inscribed on the surface of the body and the 'depth' of female subjectivity are established.

As far as the second point pertaining to penetration is concerned, a number of cases define that partial penetration amounts to penetiation for purposes of the law; that it was not necessary that the hymen be ruptured, and that the medical evidence may add to the other evidence but cannot be treated as sole evidence of rape having occurred since rape is a legal category and not a medical category. As was stated in Joseph Lines (1844) 1 C & K 393, "to constitute penetration, it must be proved that some part of the virile member of the accused must have entered within the labia of the pudendum of the girl, no matter how little.

The 1983 amendments were expected to make it easier for victims to seek redressal, and case law since then has introduced the idea that mere absence of injury on the body. of the prosecutive does not constitute evidence of consent; neither is corroborative evidence always necessary. Surprisingly the rates of conviction are steadily declining According to the statistics provided in Crime in India, the percentage of convictions in rape cases was in the range of 35 to 38 per cent between 1980 and 1986, in 1988 it declined to 8 and in 1990 to 9.1. Although many of these cases did not concern custodial rape, and several were in courts of law before the amendment was passed, one would have expected that the new directions which were given for interpreting consent, may have made conviction easier rather than making it more difficult. The question of why rates of conviction have declined is one to which I do not have a ready answer. It is worth considering, however that the underlying assumptions of judicial production and verification especially the normalisation of rape through its naturalisation—make the process of judicial reform much more difficult than was anticipated.

#### JUDICIAL GRAMMAR AND JUDICIAL SEMANTICITY

In terms of the two poles of judicial grammar and judicial semantics proposed by Greimas and Landowski (1976), we get the following taxonomy. At the pole of judicial grammar, the law defines two circumstances—the first in which rape cannot occur by definition, and the second where no judicial verification in terms of the circumstances relating to consent is necessary. The former covers cases of sexual

ntercourse between a man and his wife. egardless of the consent or otherwise of the vife. The possibility that a man could use orce to have sexual intercourse with his vife is in the realm of judicial nullity. The econd is the case of a girl below the age if 16 in which case only the fact of intercourse las to be established in order for the offence of rape to have occurred. A wife who has seen forced into submission by her husband nd a man who has obtained the consent of girl below 16, are subjects in the 'real' vorld-a reality that judges have to encounter n the courts again and again - but since the eal world is a virtual world as seen from nside the law, it needs the mediation of udicial phrases to negotiate this 'messy' eality. As we shall see later, there is a ension between judicial grammar and udicial verification so that a judgment may ake into account that a man does not have right to inflict grievous bodily harm on us wife in the process of having sexual ntercourse with her although within the imits of the judicial grammar, this cannot e classified as rape. In the converse case, when judges have encountered the evidence of a girl's consent to sexual intercourse even t she is proved to be below 16 (but not much below this age) this has been taken to onstitute mitigating circumstances for eduction of the period of imprisonment. The judicial grammar then leaves a whole lomain of sexual commerce to which the listinction between force and consent, comes o be applied in order that the difference between 'sexual intercourse' and 'rape' be udicially demonstrated. It is in the play of power here to define sex that we find that he distinctions between nature and culture ome to be articulated in order to dramatise nasculinity and femininity as capability. The following sections depend heavily upon vidence taken from modes of reasoning in he judgments in rape cases. Hence the udicial prose that has its own stylistic occuliarities, is embroidered in my prose (so o say) but I hope it retains its mark of otherness'.

#### FORCE AND CONSENT

The deployment of the concepts of force and consent in the process of judicial verification moves at two different axes constituted by reading the signs on the body and relating them to the speech of the woman is nevery case the speech of the woman is atted against her body for the production of truth. In the process of judicial verification, the judges find that either the body bears witness to the truth of the statements of the prosecutrix that she had been forced into submission, or contrarily, it provides evidence to negate the speech of the woman.

While in all cases pertaining to the violation of body integrity, it is inevitable that the body would be objectified in the process of judicial verification, here the body is objectified as a sexual body. The female body is defined in this discourse primarily as one which is marked by the impress of male bodies on it leading to a gendered reading of this process of objectification of the body.

The first question in a rape trial that the judges seek to determine is whether sexual intercourse has occurred. A whole way of talking about the sexualised body comes into play here; is the hymen intact; how much of a finger could be inserted into the vagina under medical examination; is penetration to be understood as vulval or vaginal;2 etc. Thus, a whole topology of signs is created that move on the surface of the body, territorialise it, and constitute it as a sexual body, fit or unfit for exchange. The body is objectified in ways that become a kind of judicial pornography. I give an example of this particular mode of verification on the question of whether the offence committed is to be classified as a sexual offence or is better treated as a nonsexual one.

In this case (SC 58/1986 decided on 20/ 1/1987, per P N Santhakumarı, Sessions Judge, Ernakulam, Kerala) the prosecution case was that the accused, who was 17 years old, committed assault and rape on a twoyear-old girl when her mother had left her in the care of her elder brother (seven years old) for a short while, when she went to post a letter. The mother came back and found that her son was standing in the corridor and crying. The door to the room in which the accused was with the baby was locked and did not yield to her repeated attempts to push it open. Looking through the window she saw the accused, in a half naked position, lying on the baby. He was committing sexual assault on her, having laid her on the floor while he shut her mouth with his hands. On finally being able to get into the room, the mother found the girl to be bleeding profusely. The girl sustained injury on her private parts and was rushed to the hospital.

In the medical evidence it was stated that there was a perineal tear on the private parts of the girl and profuse bleeding. The doctor had deposed that he could not examine the girl completely because she needed urgent medical care to save her life.

In arriving at the sentence in this case the judge had to decide whether the offence committed by the accused constituted rape. She summarily dismissed as absurd the plea of the defense that it was a case of false accusation. Nevertheless the judgment was that the offence was of attempted rape and

not rape proper. The following was the reasoning of the judge.

Now the question arising for consideration is whether there was penetration to the vaginal canal so as to term rape. In case of rape the prosecution in order to prove sexual intercourse, need prove penetration in the vaginal canal Penetration is enough so as to constitute rape whereas without penetration the offence or the act cannot be termed 'rape'. The girl being two year old penetration appears not easy Still there is perineal tear... There is no concrete evidence of penetration into the vaginal canal of the girl in spite of the perineal tears on the private parts of the girl which can probably be caused by criminal force. Presence of the seminal stains and human sperm heads on the girl's frock and the evidence of the mother that the accused lay on the girl does not prove penetration though it does prove sexual assault. Thus the act does not come within the purview of 'rape' as defined in \$375 IPC.

The accused having laid the girl on the floor shutting her mouth by his hands and being half naked lying against her as seen by the mother and having completed sexual act by the discharge of semen which the mother saw him wiping off from his own private parts and also from the body of the girl, the accused having taken the girl to the room and having done the act with the determination and the intention to commit the offence of rape though he had completed his sexual acts there being no evidence as to penetration which is the most essential ingredient for rape, it is only sexual assault and attempt of rape

This lengthy quotation has been given here, not because this represents the typical way in which judges define penetration—there are many other cases in which the judges have held that partial penetration is sufficient to constitute penetration under the law—but rather to show that while the same act is constituted as a sexual act for the man, there is an ambiguity as to whether a girl child's body can be treated as a sexual body in the commission of this very act.

! give one more example in which the judges came to an opposite conclusion, viz, that though the girl had not sustained any injuries the offence was that of rape. It seems to suggest that the question as to whether the girl had been sexualised by the experience is an important one in determining whether the offence is sexual in nature. It shows that the movement between surface and depth between reading the body and reading the woman as subject provides the underlying grammar of judicial verification.

This example is of a case in which the respondent/accused was a medical officer staying in a joint family. One day he tricked a young friend of his niece who was then eight years old to come to the house when he was alone with his niece. He then

on him and also slightly inserted his penis into her vulva and had an ejaculation. Although the girl did not relate this to her parents immediately since he had threatened her with dire consequences, the story came out in the next few days. On being confronted by the girl's enraged father, the accused confessed that he had frequently abused other girls in a similar manner, including his own niece. In the court the statements made by the accused were treated as extra judicial confession made in the presence of the girl's father and his own relatives. In this confession he clearly stated that he had "raped Tulna and had also committed the same kind of sexual assault on earlier occasions with Richa, Priti, and other girls of that locality, but being a doctor he had been careful enough not to rupture their hymen".

The case had come up before the High Court of Madhya Pradesh which had accepted the entire evidence of the prosecution but had nevertheless entertained a doubt as to whether the offence could be classified as rape. The High Court held that since there were no signs of injuries, on either the girl or the accused, the offence was not one punishable under either the provisions of rape or of causing grievous bodily harm, but only under Section 354 IPC on the ground that the respondent had outraged the modesty of a young girl.

The decision of the High Court created a scandal in the international press. Although the state did not prefer an appeal, the father of the girl appealed in the Supreme Court, against the judgment. In its review of the case, the Supreme Court held that there was enough evidence that the respondent "without completely and forcibly penetrating the penis into the vagina of the girl had slightly penetrated within the labia majora or vulva or pudenda without rupturing the hymen and thereby satisfied his lust after ejection of semens". The Supreme Court held that this was sufficient to constitute the statutory definition of penetration which was necessary to prove rape and accorded punishment accordingly

In contrast to the earlier case that we discussed in which the girl had suffered grievous bodily barm, in this case the girl was forced to co operate with the accused and had hence escaped injuries on the body. The accused, being a doctor bad the technical skills not to rupture the hymen. In the earlier case of the two-year-old child, the offence was declared to be a non-sexual one. In this case, the Supreme Court came to the conclusion that it was a sexual offence that had been committed.

I suggest that underlying the discussion on what constitutes penetration and hence rape, is another discourse that criss-crosses discourse on alliance. In Hindu society the young girl, with her body unmarked by the sexual desires (lusts) of men, is considered the appropriate gift in marriage that establishes alliance between men. A girl's awakening into sexuality is considered not as the work of her own desire but rather the working of male desire, which in the code of alliance is most appropriately, the desire of her husband. The sexual offence of rape against a young girl thus becomes an offence against the code of alliance - although this is only obliquely alluded to in the judicial discourse. Hence in the case of Tulna, the Supreme Court having defined the offence as that of rape, went on to state the following:

We are told at the bar that the victim who is now 19 years old, after having lost her virginity still remains unmarried undergoing the untold agony of the traumatic experience and the deathless shame suffered by her Evidently the victim is under the impression that there is no monsoon season in her life and that her future chances for getting married and settling down in a respectable family are completely married.

Without making every qualification, I would like to maintain that judgments on rape in the case of young girls (especially if a girl is a virgin), lie at the intersection of the discourse on sexuality and the discourse on alliance so that the question of whether a sexual offence has been committed, is decided not by recourse to the opposition between force and consent but on the issue of whether the body has been so sexualised by the experience as to make it unexchangeable in marriage. Thus, it is not only a matter of regarding the signs on the surface of the body but also constructing an 'inside', much as Foucault talks of the inside being in the nature of a fold. Hence, in the first case of the two-year-old child, the offence came to be constituted as one of having caused bodily injury, but not rape, although the injuries were on the private parts of the girl. While in the second case, although the girl did not sustain any injuries and her hymen was not broken because of the technical mastery over the body that the accused had by virtue (or vice) of his profession, the act was clearly defined as sexual in nature. I suggest that this may be attributed to the fact that the twoyear-old child though badly injured, was not seen as having been 'sexualised' by the act whereas the eight-year-old by having been compelled to experience male sexuality had been so sexualised as to be constantly ashamed by her experience.4 In fact the judges quoted from her account in their judgment to show that what she experienced may be appropriately termed as sexual violation. For example, she had stated that "Nawal Chacha (uncle) put his male organ

slipping out. After that my vagina was paining". The judge's reference to her feelings of shame in recalling these events shows that it is not only changes in the body but also in the construction of the self as a sexual being that determine, 'marriageability' of a girl and hence the judicial discourse dwells on her memory of the event as much as on bodily harm a constitutive of rape.

Whereas in the case of a child or a virgin the question is whether a body previously unmarked by the impress of male desire on it, has been 'sexualised' through the offence under trial, in the case of women who may be defined as 'sexually experienced', the discourse on sexuality and alliance intersects on a different point. This is the point at which a slippage occurs in which the offence against the body and will of the woman becomes transformed into an offence against the rules of alliance. These rules implicitly state that men may only treat those women as sexually available who are not integrated into the structure of alliance. Thus, those men who recognise each other in the 'matrimonial dialogue of men' to use the evocative phrase of Levi Strauss (1969), are normatively required to constitute the women as signs, as women carrying significance in this dialogue. If, on the other hand, a woman is not chaste and is therefore without significance, in the exchange between men, then she may be seen as available for sexual experimentation. In all such cases the rape trial becomes a dramatic enactment showing how force may be used against the will of the woman but is likely to h converted into consent by the application of judicial reasoning on the relation between surfaces and depths in defining the mode of being female.

The example I offer for the first kind of reasoning - 1 c, the offering of judicial protection to a woman who is integrated into the structure of alliance - is to be found in a judgment delivered by the Karnataka High Court in Criminal Appeal No 79 of 1983. D. II - II - 1986, in the case of the state of Karnataka (Appellant) and Mehabooh and Others (Respondents). The case was as follows. The prosecutrix was a married woman, normally resident in Bangalore, who had gone to another town by bus, to see her ailing father. From the bus stand she took an autorickshaw which was being driven by one of the accused. On the way the driver stopped and at his whistle another accused entered the autorickshaw. Instead of going to the residential colony, where her father lived, the driver took the rickshaw to a lonely place. The prosecutrix was threatened and bodily carried to a ditch where she was raped. The defense plea was that the absence

1 injuries on her body or on the accused showed that the prosecutrix did not resist and hence her accusation was a tissue of hes. The Sessions Court had acquitted the accused on the grounds that injuries were not found on the woman or on the accused, and there was lack of other collaborative evidence to prove rape. In an appeal against the order of acquittal, the Appellate Court held that it was possible that the woman did not physically resist for fear of being assaulted and that absence of injuries could not be onstituted as lack of proof of a sexual ittence having been committed on her. The ourt also held that it was now settled law that corroboration was not essential for conviction and that necessity of corroboration was a matter of prudence. In this case since the prosecutrix was a respectably married woman, her testimony did not need collaborative evidence. The order of acquittal was thereby reversed

This case is a good example of the manner of which femininity as capability is constructed, and how the rape trial may become a dramatic enactment of the division between a good woman and a bad woman, hisplaying norms of femininity.

The defence of the accused in this case had been that the prosecutrix had been abandoned by her husband and had taken to prostitution. They alleged that the police had a false case forsted against them and that the woman being of an immoral character, norelevance could be placed on her evidence. The defense had also relied on an earlier case (Pratap Misra vs State of Orissa, AIR 1977, sC 1307 (1977 Cri LJ 817) when it had been feld that absence of injury either on the accused or the prosecutrix shows that the prosecutrix did not resist. (We shall come to this case later).

In its judgment the Appellate Court idmitted that according to the medical officer fac woman had not complained of any pain in her private part. However "as stated by the medical officer herself further, there would be such pain or injury only if the victim is virgin and admittedly PW-1 was a married woman and used to sexual attercourse. Therefore, the fact there were orinjuries on the person did not necessarily mean either the story of PW-1 regarding are incidence was unreliable or that she was consenting party".

The judges went on to state further that Ve have gone through the evidence of PW with utmost care, particularly having in rew the defense version of the case tried to be made out affecting the character of PW but for the suggestions in the cross examination which she has also stoutly med, there is nothing to even remotely spect that she is a woman of such easy ortues".

We shall see a little later that how judges interpret the absence of injuries depends upon their understanding of the character of the woman and more precisely whether a woman 'habituated to sexual intercourse' is firmly bound within the structure of alliance or whether she can be treated as someone outside it.

In this particular case, the dividing practices by which the good woman and the bad woman are separated becomes even clearer since the judges gave an elaborate discourse on the meaning of consent. It may be worthwhile to quote this at some length.

And whilst the sands were running out in the time glass, the crime graph of offences against women in India has been scaling new peaks. This is why an elaborate rescanning of the jurisprudential sky through the lenses of 'logos' and 'ethos' has been necessitated. In the Indian case refusal to act on the testimony of a victim of sexual assault is adding insult to injury. Why should the evidence of a girl of the woman who complains of rape or sexual molestation be viewed with the aid of spectacles fitted with lenses tinged with doubt, disbelief or suspicion?.. We must not be swept off the teet by the approach made in the Western world which has its own social milieu, its own social mores, its own permissive values, and its own code of life. Corroboration may be considered essential to establish a sexual offence in the backdrop of the social ecology of the Western world. It is wholly unnecessary to import the said concept on a turnkey basis and to transplant it on the Indian soil regardless of the altogether different atmosphere, attitudes, mores, responses of the Indian society and its profile...

Having established through the means of spatial differentiation, the difference between a social inilieu which is permissive (i.e., the West) and one in which girls live in a "tradition bound non-permissive society" (i.e., India), the judges map this spatial difference onto a difference between women of two kinds. They give no less then 12 reasons why one may presume that women in India, would not make false allegations of sexual assault 'with the rare exception of one or two cases coming from possibly amongst the urban elite'. These 12 reasons define the limits within which sexual desire may move. Thus, a woman admitting to sexual assault against her would be conscious of social ostraci-sation; if she is unmarried she would appre-hend the difficulty of securing an alliance with a suitable match 'from a respectable or an acceptable family'; she would risk losing the love and respect of her husband; she would feel extremely embarrassed in relating the incident to others on account of the upbringing in a tradition bound society where by and large sex is I need not labour the point further that a woman whose testimony is likely to be believed is normatively defined as one who is 'tradition bound', who displays the appropriate modesty with regard to male desire, and who is in danger of losing the love and respect of her husband if it turns out that she had consented to sexual intercourse with another man. This brings me to the issue of how judicial logic is applied to issues of consent when the woman does not come within these defined limits, and hence violates the definition of a good woman.

I should like to take my examples of judicial reasoning of this kind from two cases - one (state of Orissa vs Pratap Misra), was quoted in the previous judgment and the second, Tukaram vs State of Maharashtra, more popularly known as the Mathura case, was alluded to earlier. It may be recalled that Mathura, a young girl who was between 14 to 16 years old had been raped at the police station while her brother and lover were outside the police station. The Sessions Court had acquitted the accused arguing that there was a world of difference between sexual intercourse and rape and that there was no evidence to support the contention of the prosecution that she had not consented to sexual intercourse. The High Court, on appeal, reversed the decision of the Sessions Court on the growads that passive submission by the girl could not be read as consent. The judgment that we shall be considering is that of the Supreme Court which reversed the decision of the High Court and set aside the conviction of the two accused

Let us see how Maihura is portrayed as a social persona in the judgment. "Mathura (PW 1) is the girl who is said to have been raped. Her parents died when she was a child and she is living with her brother, Gama (PW 3). Both of them worked as labourers to earn a living. Mathura (PW 1) used to go to the house of Nushi (PW 2) for work and during the course or her visits to that house, came into contact with Ashok, who was the sister's son of Nushi (PW 2) and was residing with the latter. The contact developed into an intimacy so that Ashok and Mathura (PW 1) decided to become husband and wife."

Following this Mathura's brother Gama had lodged a report at the police station alleging that his sister had been kidnapped by Nushi. At the police station the Head Constable asked Mathura to wait while he asked the others to move out. It was while her companions were waiting outside that the head constable took her to a torlet situated at the rear part of the police station, loosened her underwear, lit a torch and stated at her private parts. He then dragged her to a charpoy and telled her on the ground and raped her

in spite of protests and stiff resistance. After this a second constable fondled her private parts but was unable to rape her because he was in an intoxicated condition.

The main contention of the appellants before the Supreme Court was that there was no direct evidence of rape since no injuries were found on the body of the girl or of the accused. The court held that no marks of injury were found on the person of the girl and "their absence goes a long way to indicate that the alleged intercourse was a peaceful affair and that the story of stiff resistance put out by the girl is all false". The High Court had found evidence of passive submission, believing the victim when she stated that "immediately after her hand was caught by Ganpat, she cried out. However, she was not allowed to raise the cry when she was being taken to the latrine but was prevented from doing so. Even so, she had cried out loudly. She stated that she had raised alarm even when the underwear was loosened at the latrine and also when Ganpat was looking at her private parts with the aid of a torch". The Supreme Court, however, held that the cries and alarm were a concoction on her part. It said that it was preposterous to suggest that she was so overawed by the persons in authority and the circumstances that she could not resist. The judges supported the judgment of the Sessions Court including the version that "Finding Nushi angry and knowing that Nushi would suspect something fishy, she (Mathura) could not have well admitted that of her own free will, she had surrendered her body to a police constable. The crowd included her lover Ashok and she had to sound virtuous before him."

How is it that in the state of Karnataka vs Mehboob and Others, the judge made such a strong case for giving full credence to the stated version of the woman that force had been used against her, despite absence of injuries, while in the present case the Supreme Court had no hesitation in assuming that the girl had actively participated in the act of intercourse at the police station with a constable? This, in spite of the fact that her brother and lover waited outside. One has to take recourse to the structure of alliance relations within which the girl/woman was placed to see why her body was seen as if it were pitted against her speech. Mathura was already cast in the social persona of a woman who had taken a lover and hence her protests could be dismissed as a tissue of lies. In support of the judge's contention the medical evidence was read to show how habituated to sexual intercourse she was. "Her hymen revealed old ruptures. The vagina admitted two fingers easily". Thus, the reading of the surface of the body is made to confirm to the judge's reading of the 'inside' of her being - his conviction that she was a particular kind of girl who would be so overcome by her sexual desire for the constable whom she had never even seen before that she would surrender her body to him while her lover waited outside and then make accusations of rape in order to appear virtuous. Taken together, these two judgments show that judicial belief or disbelief in the woman's version of the events is a matter of the classificatory practices through which good women are separated from bad women - it has less to do with protecting the body integrity of the woman and more to do with regulation of sexuality in accordance with rules of alliance. Far from problematising the practices of sexuality in this regard, the judicial discourse normalises the dividing practices. Sexual violation becomes the opportunity in which courts of law become the sites of dramatic enactment of the judicial norms through which the relation between the surface of the body and the depth of feminine being could be read to create the female as the subject, a necesarily fragmented one since her body and speech are put at war with each other.

If further proof were needed of the classification of women suggested by the case law, one could refer to state of Orissa vs Pratap Misra. In this case a pregnant woman who was in a holiday resort with a man, was raped by some NCC students. Despite the presence of corroborative evidence, what weighed heavily with judges in pronouncing the sentence of acquittal was the finding that the man she was accompanied by was not her husband but her lover. The absence of injuries on her body was then seen as a sign of her consent and it was assumed that the man had contracted with the students to make her available for sexual intercourse. Even the fact that she had a miscarriage following this sexual assault was seen as unconnected to the event of rape.

We are now in a position to give a concise description of the classification of women that emerges in the rape trials. There is first a binary distinction between a girl who is a virgin and a woman who is sexually experienced. Desirable women are those who can be integrated into the system of alliance - virgin girls by being gifted in marriage to 'respectable and acceptable' families (to use the phrase which occurs frequently in the judgments) or those who are already so integrated. Sexual desire in these women is regulated by the structure of alliance - hence an offence against them constitutes a sexual offence for it violates the codes through which the matrimonial dialogue of men is conducted. By the same logic, however, the women who are described as of easy virtue, 'habituated to sexual intercourse' with men who are not their husbands, do not have rights to the protection of the state. In their cases the body always speaks to negate their speech. By declaring them to be shocking liars, the courts construct a category of women in whose case a 'no' to sex can be converted to a 'yes' by the application of judicial reasoning. I shall now argue further that the judicial discourse does not simply blot our such women from sight but actively constitutes them as available for the satisfaction of male lust by the judicial phrasing of the relation between surface and depth. This is the logic within which we can understand the concern of the case law to define, first, what is penetration and second. what is consent. The first re-orders the body as surface on which the judicial gaze can read different kinds of signs, establishing either complicity to sexual intercourse or resistance to it. The presence or absence of injuries, the state of the sexual organs of the woman all become evidence of where her place is in the division between virtuous and wanton women. The second question, that of establishing consent which requires inference about the will of the woman, then turns on the question of how depth or the interior motive of a woman may be establishing the surfaces of the body through the judicial gaze. Female subjectivity is made transparent as the judicial gaze moves from the surface to the depth of the body. Thus, the integrity of her being is shattered in the rape trial and the whole question of female consent becomes a 'process of positioning the male to do what comes naturally - that is to act from and in nature, in full accord with both body (desire) and speech (will)' [Bright 1994;3].

#### CONSTRUCTION OF MALE DESIRE

The discourse on male desire is veiled The judicial phrases uttered in judgments, nevertheless, show clearly that the concept of nature is deployed to first define men's desire for female bodies as 'natural', and then the classification of women that we discussed is used to direct such 'natural' desires towards the appropriate categories of women. Here too we shall see that the discourse on sexuality intersects with the discourse on alliance but the points of intersection are somewhat different.

Since male desire for female bodies is seen as 'natural' almost as a counterpart of rape being seen as an offence that does not violate the order of nature, the judicial discourse on male sexuality is engaged in the creation of a 'social savage' [Greimas and Landowsky 1976]. This social savage is tamed by the application of rules of alliance which provide the grid within which men may be constructed through their relatedness to each other. Thus, desire in the male is schooled through rules

of culture by placing men in positions relative to each other, and desire for female bodies is regulated through this social recognition that men grant to each other in the system of alliance Male desires are then judicially classified in accordance with the various points of intersection between the discourse of sexuality and the discourse of alliance

Desire for the female when embodied in a young male is classified as instinct, provided it is directed towards a woman who is not integrated in the system of alliance and hence can be categorised as a woman of easy virtue

The judicial construct of 'young male acting out his natural sexual instincts' is deployed in the sentencing structure in the course of hearing on mitigating circumstances granted to the accused. It may be evoked in the context of acquittal or even in cases when judges are laying out their reasoning as to why the offence should be treated as a grave one. Independent of the context, the judicial phrasing (emphasised in the following texts) make this construct of a 'natural sexuality residing in the male available for thought. This is particularly striking in face of the fact that women whom courts classify as of easy virtue are never seen to be acting out any natural instincts which would be symmetrical to the construction of desire in the male

In the case (SC 58/1986 Ernakulam) of the two-year-old child who was sexually assaulted by a young man discussed earlier in the paper, the assistant sessions judge gave her reasoning for reduction of the period of rigorous imprisonment as follows. 'It's indeed a cruel and wretched act to commit sexual assault or attempt to rape an infant girl of two years especially in the circumstance that the accused was sharing his stay in the residential apartment of the family of that girl along with them. At any rate the accused could have refrained from whatever his sexual instincts may be from the child Still in due consideration of the prime of youth of the accused and his tender age of running 17 at the time of the act etc'

The second case, I would like to cite is that of an unmarried woman who was raped by a hospital attendant after he had taken her to an empty room on the pretext that he was taking her to the ward where her niece was admitted. After rejecting the defense pleathat the prosecutive could not be believed because she was not a virgin and that there were discrepancies in her account the court observed.

The beastliness and atrocity of the crime is evident from the injury resulting due to the thrust. According to PW 2, the doctor, about thirty stitches were put for the ragged tear inside the vagina and blood transfusion also.

had to be given. There is no evidence of any opprovocation or enticement from the side of the victim. There is no evidence that the prosecutrix is of easy virtues. The accused is aged 32 years and the crime evidently is not the result of any impulsive act due to the intepressible sexual urge of an adolescent or youngster.

Many other examples could be given of this form of reasoning. I hope the point is sufficiently clear that in the process of judicial verification, courts construct the category of young males who are acting out their impulses and 'irrepressible sexual urges' when they rape women The judicial intervention is not directed towards the protection of all women from such males on the prowl. What the courts do through their intervention is to define the category of women on whom these urges may be acted out and separate them from the women on whom these acts may not be committed. The former are defined as women of easy virtue' while the latter are women who in future may be inacgrated into the system of alliance or are already within it

The lieve it is this definition of certain kind of sexual violence as stemming from the order of nature, which allows agents of the state such as policemen to commit rape and sexual assault on those women, who have come within their jurisdiction due to the disturbances in the code of alliance. In the case of Mathura which has a'ready been discussed, it was the complaint lodged by the brother against her lover that allowed the police constables accessover her. The judicial phrasing of the Supreme Court judgment was also based upon the fact that she had a lover she was habituated to sexual intercourse and the hymen had shown old tears. It was as if natural' for such a woman to agree to sexual intercourse with the constable whom she had not even known before, right in the police station while her relatives including her lover, waited outside In other cases of custodial rape also one common feature has been that the woman has violated the code of alliance and hence becomes a field on which men may gratify their sexual instincts

In the eyes of the courts when does sexual instinct become unholy lust? Thave suggested that this is so when the sexual act has made a girl who was previously suitable for being given in marriage now unmarriageable. We already that this is reasoning applied in the case of Tulna, the eight year old girl in that case the appellants and the defendants belonged to respectable? families—a point emphasised quite strongly in the judgment which noted that the girl's father was a journalist who had travelied abroad, and the people involved were men of 'status'. The same reasoning, viz, that the offence of rape

consisted in having made the girl unmarriageable, may be found when the accused belongs to a higher status than the girl, except that in such cases the judges may either seek to correct the injustice by insisting on a marriage between the victim and the offender or the punishment may consist of financial compensation to be provided to the girl to secure a bridegroom who would be willing to marry her

Rose Verghese (1992) cites a case (Braja Kumar Chauhan versus the state of Orissa) in which the judge first tried to arrange a marriage between the prosecutrix and the accused. After the attempt failed, the judge then reduced the sentence of imprisonment of the accused and instead fined him Rs 3,000 which was to be paid to the prosecutrix He stated that the prosecutrix 'now a young girl, will be left at lurch on account of the stigma' due to the publicity that the case must have locally received, and prospects for her marriage appeared bleak. However she could be rehabilitated, he thought if she received some financial assistance. In order to achieve this end the financial compensation was to be provided to her and the term of imprisonment of the accused accordingly reduced Clearly the courts are instrumental in 'trade off' in this case so that a man of a lower social status may be provided with the financial incentive to marry the woman who has otherwise become unmarriageable. The concern is again not with protection of the body integrity of the woman but with correcting the disturbance in the system of alliance is which has been violated by 'untained male desire

The judges are also likely to treat sexual desire as unholy lust' in cases of gang rape if the husband is present at the time of the sexual assault. This is provided, the man is recognised as an appropriate partner in the matrimonial dialogue. In one case, three men broke into a house, committed robbery and gang raped the wife one by one while the husband was held by the other two nien on the point of a knife. In the First Information Report the husband did not report the rape 'due to fear of loss of reputation" "However after the accused were identified and arrested he reported the rape saying that" his should not happen to any husband in future [Cited in Verghese 1992 159, emphasis mine] In awarding the sentence of 10 years rigorous imprisonment, the court noted the hemous nature of the crime. Although the woman had not physically resisted the rapists, the judges noted that this was "due to fear of death of her husband, herself and her child As Purvi Shah (1993 4) noted in her astute comments on the paper, "This court's decision is not based on any injury to the woman's body or lack of consent Rather it is framed within the context of the harm ier husband, tamily and she - within the ontext of her family - may face. Indeed, his woman has been made into a wife or nother rather than a woman. The cases vhereby the court renders decisions of rape nvolve subjects seen as wives not as women". the goes on to state that not only is the jusband's respectability seen as the central actor determining the court's decision in his case but also, "It is interesting to note low this privileging of the husband echoes he power granted to a father. For instance, n the rape case involving the eight-year-old, part of the case's validity stemmed from 'the all's enraged father' who was responsible or appealing the case." Thus 'natural instinct' s transformed into 'unholy lust' in judicial shrasing if acting out this instinct leads to tigmatising men as husbands or fathers. In rranging and aligning women and ositioning them in relation to men as either vailable for sex or protected within systems falliance, the courts construct and classify nale desire in a manner that leads to either he formal naturalisation of rape as somehow egally consensual or they criminalise it as hallenge to patriarchal alliance systems

Similar facts, however, of raping a woman n the presence of her husband begin to look lifferent in judicial reasoning if it turns out hat the woman was not legally wedded to he man. In the case of Pratap Mishra vs State if Orissa, to which reference was made arlier, the woman was subjected to sexual assault by three NCC cadets while on holiday vith a man. In this case the judges of the supreme Court disbelieved the version of he woman although she suffered an abortion ifter the rape and assumed consent on her part. Among other factors one, which veighed heavily with the judges was that he woman was only a 'concubine' of the nan Vasudha Dhagamwar (1992 246) in providing an excellent critique, quotes from he judgment:

We do not mean to suggest even for a moment that PW2 was a pimp, but the fact remains that the appellants undoubtedly wanted to have negotiations with him before insisting upon him to open the door. This is also a circumstance that militates against the case of rape and shows that PW2 himself connived at the sexual intercourse committed by the appellants with his concubine

One is stunned to observe in this case that what counts with the judges is the assumed elation that the men have formed with each other—the circumstance that militates against he case of rape, they say—is that PW2 timself connived at the sexual intercourse ommitted by the appellants with his oncubine. Neither the injuries on the body of the woman, nor her own will count—the smale body and will is placed in the 'custody' of the male to be disposed off as he wishes

The third construction of the rapist is of a man securing vengeance against another man by violating the latter's wife, daughter or sister. In such cases also the woman's body is merely the sign through which men enter into relationships with each other. In the Indian courts this comes up frequently in the context of policemen going on a rampage of looting, destruction and mass rape in order to punish the population of a village or a locality. Varghese (1992) quotes the case of 14 policemen who went on a rampage against the women in a small village in order to avenge an insult to one of their colleagues (Quoted in Varghese 1992, and Dhagamwar 1992) The court acquitted the policemen on the ground that the women in the village who were from the lower castes could not be equated with 'such ladies who hail from decent and respectable societies' as they were engaged in menial work and were of questionable character?. The judge further added that "It cannot be ruled out that these ladies might speak falsehood to get a sum of Rs 1000, which was a huge sum for them".

Because the naturalisation of male desire is connected to systems of alliance, the whole question of marital rape is removed from the arena of judicial discourse. The satisfaction of male desire when it is sought to be fulfilled within the confines of matrimony is considered legitimate, no matter how it is fulfilled. The legal code does not recognise marital rape - hence at the level of judicial grammar, this category does not exist. In the process of judicial verification, however, the judges can find instances when grievous bodily harm has been done to the wife in the process of the exercise of his conjugal rights by the husband. In such cases the courts have held that while a husband can cause grievous bodily harm to the wife, this cannot be classified as a sexual oftence. The first and best known case of this kind was reported in 1890 when Phulmoni Dasee who was a little over 10 years died when her husband tried to have forcible sexual intercourse with her. The husband was convicted under section 338 of the Indian Penal Code which deals with causing grievous hurt by doing an act so rashly as to endanger human life or personal safety of another. Subsequently the age of consent was raised to 12 and has continued to rise till 16 [see Dhagmwar 1994]. The law clearly takes recourse to the idea that marriage is the prescribed institution for the satisfaction of 'natural' sexual instincts - hence sexual intercourse within marriage cannot be considered a sexual offence. If a woman incurs injury during sexual intercourse with her husband this is to be treated with other non-sexual offences of a similar kind. Thus in the case of a conjugal couple, the surface of the female body has no information to convey for determining the nature of the 'inside' for she does not exist as a subject for purposes of rape law

Pratiksha Baxi (1995) argues that the discourse on marital rape, not only in the courts but also in the parliamentary debates normalised the use of force in sexual intercourse within marriage. She points out that in the report of the Joint Parliamentary Committee on the proposed amendments to the rape law, a separate category of 'illicit sexual intercourse not amounting to rape' was created to cover cases in which a man who is separated from his wife has forcible sex with her (the JPC Report 1982;8) In defence of this amendment it was stated that "The Committee feel that in a case where the husband and wife are living separately under the decree of judicial separation, there is a possibility of reconciliation between them until a decree of divorce is granted Hence, the intercourse by the husband with his wife without her consent during such period should not be treated as or equated with rape. The Committee are of the opinion that intercourse by the husband with his wife. under such circumstances should be treated as illicit sexual intercourse" [The IPC Report 1982 8, cited in Baxi 1995 73] Baxi's interpretation of this statement is impeccable "The distinction between rape and sexuality from the woman's point of view gets bluried for the state permits force in sexual intercourse, not only for describing it as normal but by normalising it for the sake of 'reconciliation'. Here power is deployed to constitute married woman's sexuality as 'passive' for the capacity to say 'no' to sex within mairriage is not recognised by the law as a legal right."

In Foucault's (1980) history of sexuality, power was understood as essentially that which dictates its law to sex by dividing sexuality between light and illight and permitted and forbidden compartments. In looking at the relation between power and sexuality as it is revealed in the judicial discourse in India, I suggest that it is encountered not in the form of limit and lack but mits dynamic active form of production of bodies and speech both male and female The sites of judicial discourse are the female body and male desire while there is a corresponding silencing of the discussion on temale desire and male bodies" \* As we have seen, it is male desire which is considered 'natural', hence 'normal' and the female body as the natural site on which this desire is to be enacted. Women are not seen as desiring subjects in the rape law - as wives they do not have the right to withhold consent from their husbands - although the state invests its resources in protecting them from the desires of other men Paradoxically

women defined in opposition to the wife or the chaste daughter, i e, women of easy virtue, as the courts put it, also turn out to have no right to withhold consent. Unlike the case of the wife, however, it is not through the application of judicial grammar but through judicial semantics that this right though legally granted is taken away in the course of court hearings. As Purvi Shah (1994:6) put it, "A reading of female desire as interpreted by the courts demonstrates that while men are seen to be acting out their 'natural' urges when engaging in 'illicit' sex, women who show any sort of desire outside the confines of marriage are immediately considered 'loose'. By escaping the confines of male-centred discourses of sexuality and alliance, these women are then castigated by becoming the objects of any sort of male desire. Rape is not a crime but is reduced to an act that she herself deserves or seeks... Under the court's adjudication of these rape cases, every man thus becomes not an object of female desire, but rather these women who show 'illicit' desire become consensual objects of male desire even against their will".

Thus it is clear that a woman's yes to sex outside marriage puts her in a position in which she is rendered judicially incapable of constructing desire in the singular for a particular man. Her illicit desire places her within the power of any man and especially within the power of the agents of the state such as policemen. It would, however, be a mistake to think that this is only a disciplining of female desire. It is equally a disciplining of male desire. By constructing male desire as 'natural' it is also generalised, so that once the system of alliance is suspended in thought, then one woman is considered as good as any other for the satisfaction of this desire. Thus the judicial discourse cannot admit of desire for a particular woman even in the male subject. One may recall the evidence of the chowkidar (watchman) of the guest house in the Pratap Misra case that he had found the man crying helplessly outside the room in which the NCC cadets raped the woman, presumably his lover. Similarly Mathura's brother and husband were made to wait outside the police station while she was raped by the constable.

Just as there seems to be no place for the woman as the desiring subject in the judicial discourse, but there is an elaborate vocabulary for describing the female anatomy and the impact of sexual intercourse on it correspondingly there is no reading of the signs of sexuality on the surfaces of the male body for establishing sexual offences, nor any understanding that desire in the male may be for a particular woman rather than for a generalised, standarised female body?." About the only question that seems medically of sexual intercourse or not and whether there are signs of injury especially on the sexual organs of the male. Both in the case of the two year old child and the eight year old child who were violated, the judges found evidence of sexual acts on the part of the male. Tulna, the eight year old child described the fattening of the penis and the pain she experienced when the man tried to insert his penis into her vulva. Similarly the judges had evidence of 'ejaculation of semens (sic)' in the two year old's case. Yet in both cases the judges only considered the question of penetration - although in one case partial penetration was considered sufficient to constitute rape while in the second case it was not. An alternate way of constructing rape would be to consider the evidence on the male body - reading the surface as conveying information on the nature of the offence - as sufficient for establishing it as a sexual offence. In that case the whole question of what constitutes penetration would become irrelevant as both male and female subjects would be constructed in their wholeness.

#### CONCLUDING OBSERVATIONS

In the introduction to this paper, I raised the question as to whether an understanding of how judicial discourse constructs normal and pathological sexuality at the level of the individual could help us to understand the widespread violation of women during episodes of collective violence and the judicial silence in the face of such grave disorders. I am not sure that we have an answer to the question but it appears to me that I may have found a possible direction towards which such an enquiry could move. If the combination of judicial production and verification (judicial grammar and judicial semantics) that we have considered produces a discourse on rape which places itself essentially on the intersection of the discourse of sexuality and the discourse on alliance, and which provides the essential function of protecting the system of alliance rather than protecting the body integrity of women, then the law can only function as long as normal classifications of marriageable and non-marriageable women; and of men who recognise themselves as partners in alliance versus those for whom such recognition is withheld since they are not likely partners in alliance; is in place. Since the the function of law turns to sort out women and position them in terms of availability and non-availability with reference to different categories of males, the entire judicial discourse falls silent in face of the collapse of these categories. This does not explain why desire to assert

relevant is whether the accused is capable • collective identity whether of nation or of community should become metamorphosed into the desire to humiliate men of other nations or communities through violent appropriation of 'their' women, but I believe that my analysis lays the foundation for understanding why the judicial institutions of the state become silent in the face of such disorder. I cannot find even the rudiments of a jurisprudence in the Indian legal system (but perhaps this can be generalised for other legal systems) that could address the problem of rape in the kinds of contexts in which the problem is not of ordering and sorting women but of protecting their body integrity against brutal rape and abduction.

#### Notes

[An earlier version of this paper was presented at the seminar on 'States of Violence', held in Michigan. I am especially grateful to the student commentators Carole McGrahanan, Purvi Shah and Stacy Cherry; and to Charles Bright for comments that proved extremely challenging in the revision of the paper. Discussions with Upendra Baxi, Pratiksha Baxi and Kalpana Viswanath were very fruitful for formulating the issues.1

- 1 I am grateful to Pratiksha Baxı for compiling the list of these cases for me.
- 2 The female body is objectified as a general body - all women are assumed to have a 'normal' body with the same kind of changes as a result of sexual activities.
- 3 Many of the cases that are analysed here are cited in the painstaking report on sentencing structures in rape cases by Verghese (1992)
- 4 Pratiksha Baxi has argued that the link between shame and sexual violence often results in rape being seen as 'worse than death' - an interpretation that she says the Indian Women's Movement has consistently tried to reject [Baxi 1995]. See also Kalpana Vishvanath (1994) who shows how the idea of shame and sexuality as a linked pair are internalised by women.
- I wonder if we can compare this with mediation in feud - another system in which men recognise each other through the exchange of violence - in which the party that is on the verge of losing may be persuaded to accept blood money to terminate the feud.
- 6 The question of how temporality enters the judicial discourse is very important, not only at the level of judicial grammar which determine how cases become time barred, but also at the level of judicial verification. Delay in the case of reporting a rape seriously prejudices the outcome not only because of the difficulty of obtaining medical evidence, but also because judges are less likely to believe a woman if she has delayed reporting the case. In the Indian judicial system the delays in arriving at a judgment (in Tulna's case the Supreme Court gave its judgment 11 years after the event) can make time itself a resource in the hands of litigants. The systematic examination of temporality cannot be undertaken here - it would require another paper.
- 7 It should be noted that when the exchange of

violence is within the framework of the institution of feud, there are strict rules which control the styles of violence that may be used. The sexual violation of women by the feuding parties is strictly considered outside the normative frame [see Das and Bajwa 1994]. What we witness in the case of policemen going on a rampage against lower caste women cannot be derived from rules of feud in which only men of equal status are said to 'recognise' each other, but a perverted theory of punishment in which the illegitimacy of state practices combine with a perverted working of caste hierarchy to produce the kind of outcome we are describing here.

- 8 This point was made forcefully by Purvi Shah (1994).
- 9 Desire for a male sexual partner is similarly generalised as an enactment of unnatural desire – an offence against nature.

### GIVE YOUR MONEY GREATER FREEDOM

RISK FACTORS: 

Mutual funds and securities investments are subject to market risks and hence there can be no assurance that the objective of the scheme can he achieved 

Performance of SBIMF in the previous schemes is not necessarily indicative of future results 

As with any investment in stocks and shares, the NAV of the Magnums under this scheme can go up or down depending on the factors and forces affecting the capital markets 

Magnum Open Fund is only the name of the scheme and does not in any manner indicate either the quality of the scheme, its future prospects or the returns 

The liability of the sponsor of SBIMF is SBI is restricted to the initial contribution 

Please read the offer document before investing in the scheme

#### HIGHLIGHTS

- High Liquidity
  - You can sell your Magnums back to the fund on any bank working day, 2t any of the 8 Collection Centres of Karvy Consultants Ltd and your cheque will be issued within 5 working days
- Repurchase at NAV for initial investment.
- Monthly Pension Plan

You can opt for a regular withdrawal of a minimum of Rs 500/. All you have to do is issue advance instructions anytime and you will start getting a monthly income.

- Dividend Reinvestment Plan
  You can reinvest your dividends
  at NAV
- Medium Risk Balanced Portfolio Well diversified portfolio comprising equity and debt investments to make your money grow prudently
- NAV declared on every working day
- Minimum subscription Rs 1000/
- No hassies of Certificates. Regular Magnum Account statements provided.
- Scheme open to NRIs and OCBs on a fully repatriable basis
- Scheme also open for Trusts, Corporate Bodies

# WHEN PRODUCTIVITY INCREASES, ALSO GO UP?

It seems logical that the more you produce the more you spend. But if you swear by productivity optimization methods, then all costs needn't go up.

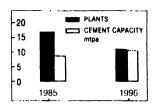

For instance since 1985, our dependence on wet process technology-to-cement manufacture—has come down trom 40 to 12 per cent in 1996.

Other achievements include better energy, conservation, improved thermal efficiency, and reduced manhours from 7.4 per torne of cement in 1985 to 2.8 today.

All this, plus, increased cement capacity from less than 7.5 mtpa in 1985 (at 17 locations) to the present 9.872 mtpa with just 11 manufacturing locations in 1996.

In a world of excesses, if you care to plug the loopholes — caring pays dividends

times change, our values don't

#### Snould Domestic Prices be Equated to World Prices?

#### Prabhat Patnaik

Much has been written in criticism of the neoclassical proposition that a country's domestic prices should be equated to world prices. The assumptions on which it is based have also been much criticised

This paper presents an altogether different argument, which is relevant in the context of an underdeveloped agrarian economy like India and which turns on the faci that agriculture has very specific characteristics different from industrial activities, to show why alignment with world prices is likely to be a patently inoptimal policy for such an economy.

A COMMONIY held view among neoclassical economists is that a country's domestic prices should be equated to world prices. Indeed two policy measures which they usually advocate, namely that an economy should be 'opened up' for trade. and that tariffs, as far as possible, should be progressively eliminated, necessarily imply between them the advocacy of an equalisation between domestic prices and world prices

The underlying argument is quite straightforward. As long as (a) the country remains a 'price-taker', (b) there are no significant non-linearities on the production side violating constant returns to scale, and (c) there is no period-wise interdependence which makes static and dynamic optimisations divergent, free trade, which necessarily equalises domestic with world prices, enlarges in every period the availability of commodities in the economy (in the sense that the economy can obtain a commodity bundle outside of its production possibility frontier). It follows that free trade is an optimal policy under these circumstances, and so, by implication, is the equating of domestic with world prices.

These three assumptions on which this argument is based may appear strong to others, but neoclassical economists do not think so. They argue that the onus of proving that non-constant returns to scale, non-'pricetaker' status and the importance of timewise interdependence are indeed weighty considerations, is on their critics, they are only willing to concede that these assumptions may be violated in particular instances, proving a case at the most for some divergence between world and domestic prices in special circumstances (e.g., the 'infant industry' argument).1

Much has been written in opposition to this neoclassical proposition. Their argument for free trade for instance has been shown 'o be a non-sequitur which does not establish he welfare implications of free trade. The fact that a commodity bundle becomes vailable which lies outside the production possibility locus only means the satisfaction of Scitovsky's double-compensation criterion. Unless however we know precisely the point to which the economy moves after trade and this point is judged to entail an improvement in distribution, we cannot, on the basis of Scitovsky's criterion alone, hold the post-trade situation to be superior in welfare terms 2

In addition, of course, the assumptions mentioned above have been much criticised The purpose of the present paper is not to repeat all that. Rather it is to present an altogether different argument, which is relevant in the context of an underdeveloped agrarian economy like India and which turns on the fact that agriculture has very specific characteristics different from industrial activities, to show why alignment with world prices is likely to be a patently inoptimal policy for such an economy. This argument is different because it retains its validity even if assumptions such as constant returns to scale, the absence of timewise interdependence and 'price-taker' are made Section I presents a simple macro-economic model, Section II shows in the context of a single period how deviations from world prices would be better from the economy's point of view, Sections III and IV look at the growth implications of the two alternative strategies and question the tenability of the neoclassical argument even in a dynamic context. Section V gives some concluding observations.

Consider an economy with just two sectors 'food' and 'manufacturing' where 'food' output is given in the short-run (one of the specificities of agriculture which yields the bulk of food) but 'manufacturing' output is subject to variations along a supply curve which slopes upwards. This upward slope is because the equipment stock is given in the short-run and output is a function of labour with decreasing marginal productivity but constant moneywage. (One can think in terms of a vintage model to make the story more credible, but the purpose of using the production function approach is precisely to remain as far as possible within the neoclassical paradigm.)

The following equations capture what has just been said

$$O_{j} = \overline{O}_{j}$$
 ...(1)

$$\begin{array}{ll} O_j = \overline{O}_j & ...(1) \\ O_m = g'(L_m), \ g' > O, \ g' < O & (2) \\ w = p_m \ g' & ...(3) \end{array}$$

$$\mathbf{w} = \mathbf{p}_{\mathbf{g}} \mathbf{g}^{\dagger} \tag{3}$$

where O denotes output, L employment, pipice, and subscripts f and m the corresponding sectors. The money wage rate was assumed for simplicity to be common between both sectors. The equations are a self-explanatory

The world prices of the two commodities are given and unaffected by the country's actions ('price-taker' assumption) The domestic prices would be nothing else but these world prices multiplied by the price of foreign exchange if the two sets of prices were indeed equated. But since our purpose is to compare a situation where they are equated with a situation where they are not. we shall use a single parameter, an import tariff on the manufactured good, to capture the possibility of divergence of domestic from world prices. We therefore have

$$\begin{aligned} P_{i} &= \widetilde{P}_{i} P_{c} \\ \text{and} \\ P_{m} &= \widetilde{P}_{m} P_{c} (1+\tau) \end{aligned} \tag{4}$$

$$\mathbf{P}_{m} = \mathbf{P}_{m} \mathbf{P}_{-} (1+\tau) \tag{5}$$

where P is the price of foreign exchange and t the tauff rate

We assume that 'food'is the export commodity and that 'manufactures' are imported. The reason why 'food' should be the export commodity need not detain us here the argument of this paper is that in economies, where 'food' is exported, equating domestic prices with world prices would be moptimal, and the fact that historically it is 'food' or other primary commodities which have been the main export items of third world countries can scarcely be doubted

The question however is, it world and domestic prices are equal for 'food', then what determines how much is exported and how much is sold at home? And if the price of 'manufacture' imports (which equals the world price when r=0) is the same as the domestic price their what determines how

much of it is imported and now much is bought domestically? We overcome this problem in two ways: (i) we assume that exports of food equal what is left over after domestic absorption of food (which is independently determined) and (ii) we make use of the identity that the trade deficit equals the excess of total domestic absorption (which is independently determined) over total domestic output.

We also assume that all wages and only wages are spent on food, and that the earners of surplus, which consists of profits and tax revenue (the only source of tax revenue is the import tariff), have a real expenditure (all of it on manufactures) which is an increasing linear function of the real surplus. On this basis we have the following:

$$M = A+b.S/P_m -O_m \qquad ...(6)$$

$$O_{f} = X = (1_{f} O_{f} + L_{m}).w/p_{f}$$
 ...(7)  
 $S = O_{f} (P_{f} = w.1_{f}) + P_{m}.O_{m} = w.L_{m}$   
 $+ M.\overline{P}_{m}.P_{e}.\tau$  ...(8)

where S denotes the total surplus in money terms, I<sub>r</sub> refers to the average labour coefficient per unit of food output (which is already realised) and the other symbols are self-explanatory. X and M, it should be noted, are reckoned in physical terms.

We have nine variables to be determined:  $O_p$ ,  $O_m$ , M, X,  $p_p$ ,  $P_m$ , S,  $L_m$ , and  $P_c$ . Once we add the following foreign exchange market equilibrium condition

$$X.\overline{P}_f = M.\overline{P}_m$$
 ...(9)

we get a complete system for the determination of all the nine variables.

Let us now turn to a description of the logic of the determination of the singleperiod equilibrium. Let us, for simplicity, take  $\tau = 0$ . For any hypothetical exchange rate we have a set of domestic prices of food and manufactures which equate them to the world prices. At that domestic price of manufactures there is only a certain amount of domestic manufactures output which would be produced (given by the supply curve) and hence a certain manufacturing employment (and consequently total employment). On the other hand, at the domestic food price, since money wages are given, we have a certain real wage, which, together with total employment, gives us the total food absorption in the economy. The excess of food output over absorption is what is exported. Imports however need not equal this figure. Since all outputs and prices are determined as indicated, we have a certain level of surplus and hence a certain level of imports (from eqn 6) which need not match these exports. There would then be a non-zero excess demand for foreign exchange (since we are ignoring all autonomous capital flows).

Looking at it differently, the excess demand for foreign exchange is nothing else but the difference between the level of surplus and the expenditure corresponding to that level. It follows then that with b < 0, the excess demand for foreign exchange would be a decreasing function of the price of foreign exchange. And there would be some equilibrium price of foreign exchange at which foreign exchange market equilibrium, and consequently overall single-period equilibrium, would be established. (An exactly similar kind of reasoning can be provided for the case where  $\tau > 0$ .)

II

We thus have alternative single-period equilibria, each corresponding to a particular value of  $\tau$ . To establish that equating the domestic prices to world prices is the optimal policy for a country we have to show that the single period equilibrium corresponding to  $\tau=0$  is superior in some sense to any other single-period equilibrium which corresponds to any positive value of  $\tau$ . Alternatively if the equilibrium corresponding to a positive can be shown to be superior to that which corresponds to  $\tau=0$ , then the vacuity of the neoclassical argument would have been demonstrated. Let us therefore compare across equilibria.

At any equilibrium the real surplus (i e, the surplus in money terms deflated by the domestic price of manufactures) is equal to the real expenditure on manufactures. But since the latter is itself a function of surplus we have the determination of surplus by this mechanism. In other words,

$$S/P_m = A+b.S/P_m \qquad ...(10)$$

from which it follows that no matter what the value of  $\tau$ , at all equilibria

$$S/P_{m} = A/(1-b)$$
 ...(11)

which is a constant. The real surplus is the same in equilibrium no matter what the level of the import tariff is.

A conclusion immediately follows from this, namely that an equilibrium with a higher import tariff must entail a higher domestic price of manufactures, and hence a higher domestic output of manufactures. If this were not the case, if the imposition of a higher import tariff were accompanied by a lower or unchanged domestic manufactures price, then the only reason could be a sufficiently lower price of foreign exchange. But, since money wages are given, a lower price of foreign exchange would necessarily mean a lower level of nominal and real surplus than prevailed earlier. This however is an impossibility because in all equilibria the magnitude of real surplus must be the

ryow, the real expenditure on manufactures (or the real surplus in equilibrium) exactly equals the sum of domestic manufactures' output and imports. Since a higher import tariff, we have just seen, necessarily entails a larger domestic output of manufactures in equilibrium, it must entail a smaller import,5 and hence, for balanced trade, a smaller export. It follows then that (i) an equilibrium corresponding to a positive level of import tariff would give both a larger level of manufacturing (and hence total) employment and a larger level of per capita domestic food availability than an equilibrium corresponding to a zero level of import tariff; and (ii) an equilibrium corresponding to a higher import tariff would be generally better on both these counts than an equilibrium corresponding to a lower import tariff (until the tariff gets so high that the basic structure of the model would have to be modified).

By contrast, there is no way that the zero tariff equilibrium can be considered superior to the positive tariff equilibrium. True, it entails a lower domestic price for manufactures, but that, apart from having an adverse effect on manufacturing output and. employment, does not even improve real income distribution, since manufactures are absorbed (in the model) entirely (and in real life largely) by the surplus earners. On the contrary, this lower domestic price of manufactures contributes towards a worsening of real income distribution because it is accompanied by larger imports of manufactures, and hence larger exports of food to achieve trade balance, which reduces domestic food availability to the detriment of the poor. It follows then that equating domestic with world prices is a patently inoptimal option for a country.

#### H

So far we have confined attention to the single-period equilibrium. It may however be thought that equating domestic with world prices, though it may have short-term adverse consequences, would be beneficial in the long run. In this section therefore we compare alternative growth-paths, each corresponding to a different value of  $\tau$ , to examine the veracity of this line of thinking.

Our strategy would be to take the singleperiod equilibria corresponding to different values of  $\tau$ , which have been discussed earlier, as representing cross-sections from a number of alternative steady-state growth paths. To do so however wse have to make a number of modifications. First, the constant term A in (6) which is given in the context of the single-period must now have a time subscript attached to it and must exhibit growth over time. We can think of it as consisting of several parts: each sector's investment which is given in the singleconsumption expenditure by capitalists whose total magnitude, we assume, grows pari passu with the total wealth, i e, capital stock, in the country; and, finally, autonomous government expenditure which is also assumed to grow with capital stock. For convenience of exposition we do not talk of government investment, i e, do not take explicit cognisance of government apital stock.

Investment in any period (we ignore depreciation) is assumed, as just mentioned, to be the result of decisions taken in the previous period. As for specific sectors, manufacturing investment is assumed to be governed by a version of the acceleration principle: investment per unit of capital stock in any period equals the expected output growth rate for that period which is an extrapolation of the preceding period's growth rate. In the food sector, as long as some threshold rate of return is obtained, the actual rate of accumulation depends not on the rate of return but on the availability of complementary inputs like irrigation and energy which the government provides. We simply assume that the magnitude of food investment in any period depends on the magnitude of total government expenditure of the preceding period which is devoted to the food sector.

Accordingly we postulate:

$$\begin{array}{lll} A_{t} = I_{ft} + I_{mt} + a.K_{t} + G_{t} & ...(12) \\ I_{mt}/K_{mt} = O_{t-1}/O_{t-2} - 1 & ...(13) \\ G_{t} = m.K_{t} & ...(14) \\ I_{t} = I_{ft} + I_{mt} & ...(15) \end{array}$$

which are all self-explanatory (a.K, denoting autonomous private consumption).

On how much of government expenditure is devoted to the food sector we adopt the following reasoning. Unlike in the single-period where capital stocks in the two sectors were inherited and nothing could be done about their relative size, in the longer run this relative size can and would be altered. The chief mechanism of this alteration is the earmarking of a larger or smaller share of government expenditure for the food sector. The government tries to maintain a balance between the two sectors (pressure from food capitalists would force it to do so), so that we have

$$\begin{split} I_n &= \alpha.d_{i-1} \cdot [G_{i-1} + b.M_{i-1} \cdot \tau/(1+\tau)]...(16) \\ d_t &= j + (\mu K_t/K_{it} - 1).t & ...(17) \end{split}$$

where d is the proportion of total government expenditure devoted to the food sector, j,  $\alpha$  and  $\mu$  are constants and M. $\tau/(1+\tau)$  is nothing else but the "real" tariff revenue (multiplied by the uniform marginal propensity to spend out of the surplus); tenters as a multiplicative term for making analysis simpler.

There are certain identities:

$$K_{f(t+1)} = K_{ft} + I_{ft}$$
 ...(18)

$$K_1 = K_0 + K_{mi}$$
 ...(20)

And finally, both equations (1) and (2) have to be reformulated:

$$O_{mt} = g(K_{mt}, L_{mt}), g'_{1,2} > 0, g''_{1,2} < 0...(2')$$
  
 $O_0 = K_0 \cdot \beta \cdot ...(1')$ 

This last point, which simply asserts the intuitively plausible proposition that food output does not increase if real wages in the food sector fall, needs an explanation. A given amount of land containing a certain investment has a certain productive capacity and utilisation of this capacity is possible with a certain labour use. Increased application of labour with a given amount of capital sunk in land cannot on its own therefore raise output. And this is why we assume fixed coefficients in the food sector.

Three possible objections can be raised against this view; each of them however is based on a misinterpretation. First, it may be thought that since labour itself can give rise to capital formation, saying that additional use of labour cannot raise output is wrong. But the production by labour of capital is not the same thing as the substitution of labour for capital a la neoclassical economics. And our assumption about investment in the food sector is that it does not depend on real wages (since the threshold rate of return is always being earned). Secondly, the change in labour application per unit area which may come about owing to the 'substitution' of machines for labour over time does not necessarily represent a movement along any production function and is not usually sensitive to the real wage rate. And thirdly, the fact of the existence of diversity among farms cannot be utilised for constructing a production function approach (along the lines of a vintage model) because any fall in real wages would not raise output on farms which have maximum labour use per unit area (and, unlike in vintage models there are no unutilised farms waiting in the wings that would become viable at the margin if wages fall)7.

The difference between agriculture and industry in this regard, why a vintage model is less implausible for industry than for agriculture, consists in the fact that in industry the marginal units are capitalist units which are at the margin on the basis of a comparison of their labour productivity with the market wage-rate. In agriculture however the marginal units are not capitalist units. They are family units where the labour productivity is well below the real wage rate anyway, so that any lowering of the real wage rate has no impact on output. This basic difference between the two situations in turn derives from the fact that concentration proceeds much faster in industry than in agriculture.

constitute the complete system. In addition to the nine variables mentioned in the previous section, this system determines in any period the following additional nine variables:  $A_t$ ,  $d_t$ ,  $I_t$ ,  $I_{ft}$ ,  $I_{mt}$ ,  $G_t$ ,  $K_t$ ,  $K_{m(t+1)}$ , and  $K_{f(t+1)}$ . The system admits a steady-state solution with uniform growth (we shall not be concerned with questions of stability). In fact the steady state rate of growth is obtained by solving:

$$a.j.[m+b.\lambda(g).t/(1+\tau)] = \mu.g.(1+g)$$

where g refers to the rate of steady-state growth, and  $\lambda$  refers to the ratio of manufacturing imports to the total capital stock in the economy which is a constant for each growth rate and is an increasing function of the growth rate itself. Now a rise in the tariff rate would, for any given growth rate, increase the l.h.s. of this equation. The equation would hold only if the growth rate itself increases as a consequence of the tariff increase. In other words, the rate of steady state growth associated with a higher rate of tariff is higher than that associated with a lower rate of tariff. The argument that deviations from world prices, though possibly harmful in the short run, are beneficial in the long run is not therefore a valid one.

#### IV

It may be useful to see heuristically why a higher tariff rate would be associated with a higher growth rate in the economy. By our assumption the government is maintaining a certain balance between the sectors in the economy. Along each steady state path in other words the sectoral distribution of capital stock remains the same. If we compare these paths cross-sectionally, i.e., along a slice of time, then they would differ with respect to the tariff rate, and as a consequence there would be differences in the rates of growth which, cross-sectionally, would appear as diferences in A (see Section II). In other words, a higher tariff rate's increasing the growth rate reflects itself as an increase in A. Suppose there was no such increase in the growth rate, i e, A remained the same across paths even as the tariff rate increased. Then the surplus per unit of capital stock would remain the same across all paths, and total absorption and investment per unit of capital stock would remain the same. A redistribution of surplus would take place away from the food capitalists (owing to the terms of trade shift) but this would have no effect either on the magnitude or composition of aggregate demand.

If this shift of surplus, of which the government would be a beneficiary, leads however to an increase in its spending, and if investment in the food sector depends not so much on the surplus of that sector itself (since the threshold rate of return is being

spending, then clearly the result would be an increase in investment per unit of capital stock, 1 e, in the growth rate. This is the reason why an increase in the tariff rate, which has the immediate impact of raising employment and food availability, has the long-term impact of raising the growth rate (since the two analyses are carried out separately we cannot as yet get a complete picture of the traverse and hence cannot put the results of the two analyses together).

#### V

Finally, we have to ask: why do the conclusions of the present paper differ from standard neoclassical fare? An obvious reason for the difference arises from the assumption of fixed money wage that we make. This underlies the existence of unemployment in the economy, which makes possible larger or smaller output in one sector (manufacturing) even for a given output in the other sector (food). This is in contrast to the commonly-made assumption in neoclassical models that the money wage is flexible and its equilibrium value is that which clears the labour market. And if the economy always experiences full employment then movements can only be along a production possibility locus, and the question of any policy giving rise to larger employment simply does not arise

But our departing from utterly unreal neoclassical assumptions like flexible money wages and perpetual full employment is only one element in the picture. The specificity of our model, which is not just a restatement of the well-known view that in a demand-constrained system protection raises employment, arises from an important additional element which has to do, as mentioned earlier, with the difference between agriculture and industry. Three aspects of this difference are pertinent here.

First, agricultural output, unlike that of industry, is unaffected by demand and hence price in the short run, and the same within limits can be said of agricultural supplies (we are ignoring the question of speculation here). Secondly, not only is the output of the agricultural sector not demand-determined in the short run, but its productive capacity cannot be easily augmented in the short run through the shift of resources from elsewhere. To be sure this is true within industry itself: unemployed resources do not easily migrate from one industrial sector to another; but this is even more true between agriculture and industry.

These two characteristics imply that agricultural output is fixed in the short run, and in an economy which is an exporter of agricultural products, the domestic availability of such products in the short run is inversely related to how much is exported.

The agricultural product whose availability is of crucial importance is of course food. Since the substitution of non-food for food crops can be effected with great rapidity, it follows that the short run availability of food in an economy with agriculture as the main exporting sector is inversely related to the magnitude of exports.

It is this proposition which underlies our argument in the short-run context for deviating from world prices. If tariff protection of industry enlarges the output of this sector resulting in lower imports, then a foreign exchange market equilibrium can be achieved with lower levels of agricultural exports as well which means that there is an increase not only in total employment but also in per capita food availability.

Every such tariff imposition however shifts the terms of trade against agriculture, and our presumption is that this shift in itself has no adverse effects on private investment in agriculture. The reason for this lies in the third characteristic of agriculture, namely that while a certain minimum profitability constitutes a condition for investment, once this is ensured, raising profitability further does not have any positive effect on private investment. What private investment depends on (once the minimum profitability is ensured) is the availability of complementary public investment in the form of infrastructure, irrigation, extension, etc. To say this is not to assert some unique relationship between public and private investment (since how much of private investment is stimulated would depend on a host of additional factors including land relations and the available technology); it is to suggest that terms of trade per se, except in extreme situations, do not necessarily have any bearing on investment<sup>9</sup>. And it is this presumption which underlies our conclusion from the comparison of long-run growth trajectories, each of which is associated with a different rate of tanff protection, and hence a different level of the terms of trade.

The proponents of 'liberalisation' in agriculture fail to see this point. Their argument is that higher profitability in agriculture would lead to higher investment irrespective of what the state does or does not do. As a matter of fact it is only what the state does, and not higher profitability as such, which would determine whether agriculture experiences higher investment. It is this last proposition which underlies our argument about the desirability of deviation from wor'd prices even in the long run.

### Notes

1 Often a weaker version of the neo-classical proposition is advanced which argues that it is not the absolute levels of domestic prices which should be equated to world prices but that domestic price-ratios should be made equal to world price-ratios. In the absence of

- does not augment availability in any period: the availability frontier can be different from the production possibility frontier (lying outside it but touching it just at the point of production) only if there is actual trade. But if actual trade takes place, then either the absolute prices tend to get equalised, or the inequality between the domestic and world prices is maintained through a system of tariffs and subsidies (which amounts to de facto depreciation of the currency and hence de facto equality of absolute price-levels) Thus, the distinction between equalising the two sets of price-ratios and equalising absolute prices is scarcely of any practical consequence.
- 2 This argument is based on that of none other than IMD Little in his A Critique of Welfare Economics, Oxford, 1951
- 3 The broad setting of the argument of this paper, though not the argument itself (nor the details of the model), is similar to that contained in my paper 'Trade as a Mechanism of Economic Retrogression', forthcoming in the Journal of Peasant Studies.
- 4 The assumption of linearity is not necessary but is made for convenience. But the assumption that expenditure corresponding to surplus is a function of the magnitude of surplus alone is somewhat strong (though much less so than commonly used assumptions like proportional savings) because it presumes that the marginal propensity to absorb manufactures as the surplus increases is the same for the capitalists in the two sectors as well as for the state While dropping this assumption does not within limits, negate the results obtained below, it makes the argument more messy
- 5 This of course holds because A is a constant If for some reason A increases, then, for any given t, M is likely to increase, but the increase in M can never be as large as the increase in A, since that would entail a constant O<sub>in</sub> which is an impossibility an autonomous increase in a gregate demand must make its impact felt via some increase in prices and hence output
- 6 There is no harm in adopting this procedure since productive spending on overheads, even when it leaves behind a tangible asset scarcely yields a return and employment on these assets is largely for maintenance and repairs, commercial investment by the government can, if one so wishes, be treated on a par with private investment
- 7 While Amartya Sen's original explanation of the inverse relationship between the size of holdings and productivity talked in terms of a common production function between large and small farms. Utsa Patnaik emphasised the different production possibilities available to the different groups of farms. My argument here amounts to saying that for each group there are, as it were, fixed technical coefficients, and a change in real wages does not either alter the relative weights of the groups or bring in hitherto unutilised production capacity. See A K Sen, 'An Aspect of Indian Agriculture', The Economic Weekly, Annual Number, 1962 and Utsa Patnaik, 'Neo-Populism and Marxism', Journal of Peasant Studies, 1979.
- 8 While this is an obvious proposition we could not infer from it that an optimal policy would entail deviations from world prices Protection for raising employment could be provided by exchange rate depreciation alone as in standard "beggar-my-neighbour" formulations, without necessarily involving any tariffs.
- 9 This proposition was argued forcefully in Ashok Mitra's Terms of Trade and Class Relations, Cass, London, 1977.

## Export-Oriented Agriculture and Food Security in Developing Countries and India

### Utsa Patnaik

The set of economic policies labelled economic liberalisation, stabilisation and structural adjustment adopted by developing countries over the last 15 years have had and are having a profound impact on the nature of the development process in these countries, and especially on their food security. It is the aspect of food security as affected by food availability and income shifts which is the focus of this paper.

The paper argues that the undeclared aim of these policies appears to be the restricting of domestic income growth and absorption of the products of developed countries by the populations of developing countries in order to release resources for growth of the exportable products demanded by the developed world. In support of this the paper looks at the international division of labour in agricultural production in a historical perspective and contends that the theory of comparative advantage cannot explain either the history or the pattern of international specialisation because it contains a logical fallacy relative costs cannot be defined at all for a large range of trade relations. The paper also comments on the new pattern of demands on tropical agriculture emerging in the developed countries and the new drive to obtain tropical importables on favourable terms.

DURING the last 15 years, 1980 to 1995 nore than 80 developing countries have been following over various sub periods a sirtually identical package of economic policies, labelled 'economic liberalisation stabilisation and structural adjustment programmes, under the tutelage of the international lending agencies - the International Monetary Fund (IMI) and the International Bank for Reconstruction and Development (World Bank) They have done so as the obligatory condition imposed on them for portowing in order to finance their external payments deficits. Such a comprehensive orchestration from metropolitan centres of policy measures with an identical overall thrust for developing countries across the globe, is unprecedented and has never been seen before in the post-war era. These policies have had and are having a protound impact on the nature of the development process in the countries concerned, and on their food security in particular. It is the aspect of food security as affected by food availability and income shifts on which we propose to focus in this paper

India is a relative later omer to the group of adjusting countries in that the Fund Bank determined package started being implemented from mid-1991, the macroconomic impact of the policies, though redictable on theoretical grounds and on the basis of the experience of other countries is showing up in the data sources only with considerable lag, though in some respects the direction of the impact is already quite cear. In discussing the impact of the policies the agrarian sector and on food security 11 India, we will therefore draw upon the perience of other developing countries, while supplementing it with the available Il formation on the trends in the domestic onomy

This paper is in three parts. In the first we discuss the main content of the Fund Bank administered policies and argue that even though the ostensible aim is the correction of external payments imbalance and structural reforms required to sustain this the policies themselves are internally contradictory and not consistent with this declared aim. They do appear to be fully consistent however with the undeclared aim of restricting domestic income growth and absorption of their own products by the populations of developing countries in order to release resources for growth of the exportable products demanded by the developed world. They are also consistent with opening up markets for metropolitan capital where substitution of domestic productive capacities by imports rather than income expansion, appears to be the main mechanism of securing larger markets

We argue that the rationale of the first objective emerges clearly when we look at the international division of labour in agricul tural production in a historical perspective The climate soils specificity of crops and the concentration of natural bio diversity in tropical and sub-tropical areas has led historically to a high degree of import dependence by developed countries on imports from these regions and their policy regime vis a vis third world agriculture has been geared accordingly to sustaining their imports based high living standards. The populations of northern countries have made continuous and sustained demands on the limited productive capacity of tropical lands while the converse has not been true. The theory of 'comparative advantage' cannot explain either the history or the present pattern of international specialisation because it contains a logical tallacy relative cost cannot be defined at all for a large range of trade relations

We argue that despite some advances in productivity in the third world and in biotechnology in advanced countries, to date the sustenance of imports dependent high living standards in the latter appears to have been possible only at the expense of the decline of basic foodgrains production for local third world populations. It is in this respect that there is a strong adverse effect on food security. The emerging inverse relation between food production and exportable production is a pan developing countries phenomenon which is particularly marked in those which have taken structural adjustment loans in the 1980s and have been pushing agri exportables for a number of years. The inverse relation is just beginning to emerge in India as well

The second section comments on the new pattern of demands on tropical agriculture emerging in the developed countries during the last two decades and the new drive to obtain tropical importables on favourable terms. It argues that the present economic policies (SAP with trade and investment liberalisation) objectively achieves this aim whatever the putative aim might be by restricting domestic mass consumption growth in the third world countries against a cenario of declining investment, and through opening up of the agrarian economy induces cropping pattern and product use shifts away from basic necessities for local populations. Food security is seriously undermined and in countries which started with low iverage levels of nutrition prefamine conjunctures are rapidly created. Any moderately severe economic shock is then enough to plunge the vulnerable into actual starvation

The third and last part briefly explores the emerging class dimensions of support for and opposition to the new policies in India.

## Putative and Real Agendas in the Agrarian Sector

The new economic orthodoxy which has been introduced globally, by now is so well known as to require only the briefest recapitulation. It involves at the national level the apparent 'withdrawal of the state' from economic activity: however an essential aspect of this 'withdrawal' has been unprecedentedly vigorous and active state intervention to reverse previous policy packages and introduce completely new ones; far from being passive, the state actively implements a new policy package under Fund-Bank tutelage. Short- to medium-term measures include very tight fiscal and monetary policy amounting to sharp domestic deflation, devaluation, removal of protection (trade liberalisation), removal of subsidies; longer run measures include opening up the economy to the free inflow of foreign capital, privatisation of public-sector enterprises including the financial sector, removal of exchange controls and eventually full convertibility, export promotion and in the agrarian sector encouragement to agriexports and commercial agri-business.

While all this is put within a framework of the desirable, 'efficiency' promoting effects of the free operation of capitalist markets, this is evidently something of a smokescreen, in that a reified notion of 'the efficient market' is used to validate specific packages of interventionist measures which have never been implemented in this form in the developed countries themselves even when they had payments imbalance problems, but are today exclusively applied to developing countries. The benefits of these policies in turn accrue exclusively to the global metropolitan sector.

The core of the new economic dispensation, then, is deflationary contraction of the economy combined with the privatisation of industry and infrastructure, and the dismantling of all controls and protection in the process of promoting 'liberalisation', that is the unrestricted inflow of goods and capital. 'Deflation' is to be understood as income deflation and not price deflation; indeed rapid price inflation in necessities like foodgrains is a preferred instrument of mass real income deflation in many cases including in India. (While pushing for the full liberalisation of trade and investment flows into indebted countries, even the most ardent northern liberalisers do not however advocate the free mobility of labour or question immigration restricting policies in their own countries). To sum up, the policy package extends in fact far beyond the requirements of correcting external imbalance alone; the latter is used as is a validating device to bring in a total reversal regime hitherto followed.

Let us see what the IMF itself has to say about the policy measures actually implemented under its guidance by 78 indebted countries in the course of the 1980s.

It is evident that demand-contracting measures were undertaken in almost all cases and wage restraint plus exchange rate adjustments in a majority (Table 1). The cuts in central government expenditure and reduction in the budget deficit ratio, as is well known by now, were almost invariably achieved by slashing productive investment and cutting outlays on health and education. These were the logical corollary of the emphasis on the reduction of state investment. privatisation and the promotion of market pricing of health and education services. Now income deflating, demand-contracting fiscal and monetary policies have been timehonoured though crude and painful ways of reducing imports and thus helping to correct an external deficit. When an entire population's average income falls owing to deflation, it is obviously forced to consume, save and import less. In a developing country where average income is low and the distribution of income is highly skewed to begin with, income deflation has serious results: there is higher unemployment, and poverty increases further from already high levels. This happens even with unchanged income distribution owing to the fall in average income; in addition regressive fiscal and other policies (lower tax rates on the well-to-do, cuts in social subsidies, wage restraint) also worsen income distribution. Public goods availability suffers with social sector cuts.

But is it really necessary to incur such a high economic and social cost which is mandatory with a generalised deflation? Many economists not subscribing to the current economic orthodoxy have argued that it is not necessary: the desired effect of reducing imports and improving the trade balance, can in fact be obtained at very much lower social cost by specifically targeted export promotion and import controls, and through a system of allocating scarce foreign exchange to priority uses. The associated internal budgetary balance can be improved, not by growth-reducing cuts in investment and in vital social sectors, but by widening the tax base, ensuring less evasion and by cutting unnecessary state expenditures. Generalised deflation of the economy is not necessary for the desired end; it has been like ed to trying to cure a headache by cutting off the head.

#### **EXPERIENCE OF ADJUSTING COUNTRIES**

A well known set of UNICEF-sponsored studies [edited by Cornia, Jolly and Stewart 1987] on the impact of SAP and liberalisation on capital formation, growth and human

development indicators, have unfolded damning indictment. In 55 countries impl menting SAP during 1980-85, out of a tol of 124 years for which data were available in 71 years change in real investment rai were either negative or showed negligit change compared to the previous year; o of 186 years, in 155 years GDP per cap either fell or showed insignificant chang In a majority of countries, proportionate more so in Africa and in Central Americ poverty levels rose, as did infant mortali rates, while literacy campaigns received setback as health and education outlays we cut sharply under the mandatory Fund-Ba requirement of reducing governme expenditure [Pinstrup-Andersen, Jarami! and Stewart 1987]. However much the Fun Bank might protest that it does not speci that productive investment and the soc sectors be cut, the signals it sends c regarding the desirability of the withdraw of the state from investment, privatisaton hitherto public-sector enterprises, and 'rational' market costing of health a education services, are all consistent w public expenditure cuts necessarily taki these forms.

A more recent paper by R van der Hoev (1994) summarises the latest IMF studies Latin America. Taking all countries whi implemented liberalisation and adjustme between 1980 and 1990 the per capita Gl declined by 9 per cent, the minimum wa by 31.7 per cent and agricultural wage 26.5 per cent. The proportion of the po rose from 41 to 44 per cent with a large impact on the urban poor. The averag naturally conceal large variations with a fe countries performing reasonably and other approaching disaster scenarios with up to per cent decline in per head income (Boliv Argentina, Guyana, Haiti, Nicaragua) wh countries like Chile, Colombia and Barbac have seen stagnation in per head GDP. T absolute numbers of people in poverty Latin America have increased by 45 per co from 91.4 mn to 132.7 mn over the deca [Psacharopoulos 1993]. The cold statist conceal acute social distress: in so. countries worst affected, bizarre sympto of social tensions have emerged, as in Bra where large numbers of urban child begg

TABLE 1: IMF-Supported Programmes in 78 Countries in 1980s

| Type of Policy                 | No of Case<br>(Per Cent of To |  |  |

o have re-emerged as the destitute give up heir freedom in return for subsistence

The IBRD data on sub-Saharan Africa. show that during the decade 1980-1989 out of 33 countries, 12 countries with 40 8 per ent of the population of the region registered average annual per head GDP decline ranging from zero to 2 per cent and another nine countries with 40.4 per cent of total population registered declines exceeding 2 per cent per annum Thus 81 2 per cent of he total population of sub-Saharan Africa n a total of 42 countries, experienced fall n income per head, taking all 46 countries of the SSA region as a whole per head GDP lell by 1 1 per cent annually over the decade Since the clites in African countries protected heir incomes, the decline for the rest must nave been larger. As a part of Fund guided wage-restraint policy, real average and minimum wages were cut by a quarter over just five years, 1980-85 in two-thirds of the countries for which wage data are available (IMF reports, summarised in van der Hoeven

Such sharp mass income deflation over such large populations, is unprecedented in the post independence history of developing countries, nor is it a matter of a few years of adjustment after which the economy starts growing again on the contrary since the basic problems of external imbalance and increasing indebtedness are not solved but aggravated by SAP policies the indebted cconomy enters on a permanent merry go round of more income deflation more devaluation, more raising of interest rates for fear of hot money flight more poverty for the masses combined with a more import dependent consumption for a minority towards whom the income distribution shifts In Latin America and SSA this has been going on now for a decade and half

Both regions, the Latin American countries is well as sub-Saharan Africa have seen a highly successful' export drive in primary products which has served to push out increasing volumes of exports to the advanced countries 'Successful' from the point of view of the latter, but not from that of the former, since sharply declining international terms of trade for primary products relative to manufactures (a minimum of 50 per cent decline in the 1980s continuing into the 1990s) have meant that any African developing country which 'only' double dexport volume wer the decade, was left with no increase in exchange earnings at all. The successful' xport thrust was therefore accompanied by worsening trade balances, since imports were imultaneouly liberalised while terms of trade noved adversely

These trends should cause no surprise when the same policies of devaluation and primary exports thrust are strenuously pushed

developing countries which are thus made to compete against each other to augment world supplies, it is hardly surprising if international prices decline, particularly since there is no sharp expansion of demand in importing countries. On the contrary the advanced countries economies continue to register stagnation or low growth under the regime of the high interest rates demanded by finance capital. For the African countries during the last 15 years, the decline in external terms of trade has amounted to a collapse which continues into the 1990s. We will have more to say on terms of trade in relation to India later. For the importing developed world on the other hand these price trends combined with successive rounds of Fund pressured devaluation in the exporting countries, have meant continuously lowering dollar prices for a range of necessities these countries cannot produce and has helped them to maintain and even raise their real standard of life despite their own very low rates of income growth. It is hardly surprising that there is a veritable cacophany of theories emanating from northern universities which castigate the poorer countries, alleged, export pessimism' urge them to open up and export usually the examples of 'export success are drawn from the state interventionist, neo mercantilist countries like Taiwan, South Korea or Singapore none of which are debt constrained SAP implementers and aic therefore totally irrelevant to the case of those developing indebted countries of which India is a prime example

Lund-Bank income deflating policies in poor indebted countries, despite being widely criticised for a decade on the basis of their own data for reducing investment and growth increasing poverty and leading to regression in health and education indicators, continue today to be geared to imposing the same punishing regime of income and demand contracting measures India as a recent entrant into the group of adjusters, has been implementing exactly the same set of policies. All the talk of 'adjustment with a human face has not changed by an iota the basic agenda. The package India has been implementing from mid-1991 is no different in substance from the packages implemented from a decade earlier by countries in sub Saharan Africa and in Latin America, with very adverse results, as we have seen

### DOWNWARD SHIFT IN FREND INVESTMENT AND GROWTH RATE UNDER SAP

The first act of the governing regime in mid-1991 was to devalue the rupee by 25 per cent and after allowing the exchange rate to slide further one of its last acts in the course of 1995 has been to carry out a further

the existence by then of large reserves, in total the rupee has depreciated against the dollar in nominal terms by over 50 per cent since 1991. In between it has imposed deflationary income contraction on the economy, engineered inflation in necessities prices, and slashed social subsidies which taken together have increased unemployment, reduced investment and growth, cut the real incomes of the masses and raised poverty

As in dozens of other countries earlier in India too both public and private productive investment and the social wage have seen severe cuts since 1991, resulting in a downward shift in the growth rate of the economy and a rise in poverty. The most severe income deflation was applied in 1991-92 and 1992 93 with the reduction in the ratio of the fiscal deficit to GDP from 8.4 per cent to 5.9 per cent and large administrative price hikes especially in issue prices of foodgrains under the PDS. The total capital expenditure of the central government declined by 16 per cent to 20 per cent in real terms (depending on the price deflator used) over these two years alone. The economy stagnated in the first year at grew by 5 per cent in the next year but this was mainly because of good agricultural performance. The rise in administered food prices led to a phenomenal increase in poverty by 1992, especially in rural are is to 48.1 per cent compared to 36.6 per cent. In 1990-91 according to the Tendulkar Jain (1995) estimate

In 1993-94 and 1994-95 however the budget deficit to GDP ratio rose above the desired SAP compatible levels attracting warnings from the Fund Bank but the expansionary effects were limited by the fact that it was the resenue deficit which grew fast at the expense of continuing stagnation in productive investment. However, some expansionary effect was present nonetheless and the growth rate improved though it remained at less than half of the annual rate for every one of the eight years before SAP. Also, this growth as the mere partial recipturing of the development loss of the preceding two years did not represent a net.

gain. Indeed the Net National Product per head rose by an annual average of a mere of 9 percent over the three years starting with 1991-92, compared to 5.7 per cent the three years peceding the reforms (Table 2) according to the data in the official 1994-95 Economic Survey. Poverty incidence came down by 1994 as the inflation rate moderated but it was still noticeably higher than in 1989-90, as confirmed by the Sen-Chandrasekhar estimate. With the general elections approaching fast the deviation towards SAP-incompatible higher budget deficit ratios has necessarily continued into 1995-96.

Manufacturing growth in particular has decelerated severely. A simple average of annual growth rates gives 1.9 per cent for the first three years of the reforms, 1991-92 to 1993-94, compared to an average of 7 4 per cent during the preceding six years 1985-86 to 1990-91 calculated on a similar basis (Table 3). With the SAP-incompatible rise in the budget deficit ratio, the growth during 1994-95 was much higher at 8.5 per cent (and for 1995-96 it is claimed to be even higher); even so however the four-year average starting 1991-92, is less than half of the average for the years preceding the teforms.

The trade deficit is expected to be back to about \$5 billion in 1995-96, which is short, but not much short, of the \$ 5.9 billion of 1990-91, despite significant export growth in the interim. The reason lies in a surge in imports in the last couple of years, partly owing to the industrial expansion but partly also owing to the import liberalisation that has been a feature of structural adjustment. It is noteworthy that the composition of imports is changing towards the particular types of 'capital goods' required for the new durable consumption goods. This again replicates the experience of other developing countries under liberalisation; however much export growth is hiked, freeing of imports particularly of the non-developmental kind leads to a private spending spree by the well to do, so that in a few years the payments problem is usually back to square one, while in the meantime a high and quite unnecessary price has been paid by way of more poverty for the rest of the population. The decline in the savings rate in the Indian economy is consistent with this spending spree by the

Inflation, stimulated by the 25 per cent devaluation of the rupee in 1991, was added by the cut in fertiliser subsidy in August 1991 which raised fertiliser prices by 30 per cent, and by effective cuts in food subsidy was months later when issue prices for 1900dgrains from ration shops were raised sharply. A record rate of inflation, of 22 per cent (last month basis) for agricultural abourers, resulted. In the face of criticism

about the impact on grain output, the fertiliser price hike was partially reversed; but the damage is beginning to show up in stagnating food output. Research yielding some regional field data shows a sharp decline in 1992-93 in value added per hectare and per worker owing to input cost rise.

The total rise in the official index of wholesale prices over the four years of the new policies has been over 50 per cent. which is very high by previous Indian standards. For the wage-earners in the informal sector and labourers in agriculture the rise has been much higher: the consumer price index for agricultural labourers has risen by 70 per cent over the four years. Since the major part of the wage-paid workforce has no indexation of earnings to inflation, its real earnings decline has been substantial; perhaps this is one reason the Central Statistical Organisation appears to have stopped giving the break-up of GDP by factor incomes.

The Indian experience so far has replicated the familiar contours of the experience of adjusting countries in the 1980s: reduction in the growth rate, especially of industry; very substantial real income decline through the route of necessities prices inflation affecting the wage earners and the poor who are net purchasers of food, pushing more people below the poverty line. The export growth rate has shifted upwards but so has the import growth rate. We will argue later that rapid export growth especially of agricultural products far from being a positive indicator, under conditions of stagnating overall investment can only be at the expense of decline in mass domestic consumption of basic foodgrains. The only concession to criticism has been talk of 'safety-nets' for the poor as part of 'adjustment with a human face', but there has been no change at all in the basic agenda of reducing growth. (The analogy might be of a person with a limp who is advised to cut off a portion of her good leg in order to ensure stabilisation of gait and is then generously offered a set of crutches).

The implacable, relentless insistence on the growth-reducing and poverty-increasing agenda, in itself suggests that however welldocumented their adverse effects on the general population in developing countries. these policies will continue to be mandatory because they have been highly successful in implementing the real, as opposed to the putative Fund-Bank agenda, where the real agenda is viewed as expressing primarily the economic interests of the developed nations. We argue that reduction in the rate of growth of income and hence of demand in the developing countries serves a definite positive function favourable for the capitalist developed countries in the present conjuncture, for the economic disenfranchisement of the majority of the third world population benefits them. This strong proposition is advanced not hastily but advisedly, after looking at the evidence. Why and how restricting growth in third world countries benefits advanced countries, is a question we explore for the agrarian sector. Before that, let us briefly recapitulate the existing estimates of poverty in India.

#### INCREASE IN POVERTY AND IN IMR

Given the marked downward shift in the trend growth rate of the economy over the last four years of the new policies, and the rise in the rate of inflation which erodes the real incomes of the unorganised labour force, not surprisingly the incidence of poverty has risen quite sharply. The findings of Gupta (1995) and Tendulkar and Jain (1995) confirmed this for a comparison of 1990 and 1992. Both showed substantial rise in poverty

TABLE 4: ESTIMATES OF RURAL POVERTY

| Year    | Number (mn) | Poverty Ratio |
|---------|-------------|---------------|
| 1987-88 | 229 83      | 39.28         |
| 1989-90 | 208.79      | 34 41         |
| 1990-91 | 216.50      | 35 ()4        |

incidence. Data from the new quinquennial survey for 1993-94 have been since processed by the Planning Commission to show that between the two quinquennial surveys, 1987-88 and 1993-94 poverty has declined and this finding has been used by proponents of structural adjustment as proof of the beneficial impact of the new policies on poverty.

However 1987-88 is the wrong base for comparison, being both an exceptionally poor agricultural year and also too far back from the date of initiation of the 'reforms'. Also, the Planning Commission used a traditional, questionable methodology which had been criticised by an Expert Commission, namely, it took the difference between the CSO aggregate consumption estimate and the lower NSS estimate and distributed this difference over each NSS expenditure group in the same proportion as that group's share in unadjusted consumption. There are reasons to believe however that the extra consumption not captured by the NSS is likely to be skewed towards the higher expenditure groups. Upon rectifying these defects, Chandrasekhar and Sen (1996) find that rural poverty (similar estimates for urban poverty have not been made) which was on a downward trend has started rising again and in each of the post-reform years has been higher than either in 1989-90 or 1990-91 (Table 4).

The Indian experience during the last four years thus substantially replicates the experience of dozens of other countries: reduction in investment and growth, and rise in poverty. The infant mortality rate which is a telling indicator of the level of mass well-being, registered a slow but steady decline all through the late 1980s, but during the reform period, 1991 to 1994 the rate of decline has slowed down and in a number of states the urban IMR has actually risen (Shiva Kumar, A K, 'Urban IMR and Economic Reforms' in Frontline, 1996). States in which urban IMR has been stagnant or has risen include Rajasthan, Haryana, Uttar Pradesh, Bihar, Karnataka and Tamil Nadu, many had higher than average IMR before the rise.

At the same time, there have been larger inflows of foreign capital, about three-quarters of it in the form of mobile 'hot money' attracted by high interest rates, and a large accretion to reserves — not arising, it may be noted, from any export surplus, but arising substantially from borrowing. To this extent the very source of larger reserves carry a hefty interest burden.

Large reserves are a cause for satisfaction if they permit a bolder programme of state investment for development than would otherwise be possible, as was the case for example with sterling reserves accumulated by India during the the second world war

which permitted the bold Second Plan of much higher state productive investment, since these sterling reserves provided a buffer against the inevitable external payments imbalance accompaying growth. Accumulating large reserves makes very little economic sense however if a state-led investment thrust is anothema under SAP as at present; on the contrary the Indian state is required, and it has already obliged, to deliberately emasculate itself by cutting its own productive investment, privatise PSUs and to start scouting for foreign finance capital. Rise in external debt - a significant part of which falls in the category of 'hot money' - and increased vulnerability to speculative capital outflow are the result. By early 1996 India's external debt has reached the third largest size in the world at nearly a hundred billion US dollars (exceeded only by Brazil and Mexico) and servicing this debt is expected to absorb an increasing share of export earnings. From the third quarter of 1996 as the phased principal repayment of structural adjustment loan taken in 1991-92 falls due, the pressure on the balance of payments will increase sharply. We may expect a scenario of further pressure by the lending agencies for more devaluation, more liberal imports and further exportvolume increases in the coming months, which will be quite compatible with further worsening of current account deficits and further rise in indebtedness.

These policies are hardly rational from the viewpoint of the mass of third world populations; they continue however to be pushed strenuously by the Fund-Bank and continue to be implemented by indebted third world governments. The only rational explanation seems to be in the undeclared but transparent agenda, namely, their usefulness in accessing and cheapening third world exports for consumers abroad, and opening up hitherto protected third world markets.

There are strong incentives which are offered by the new policy regime to the minority constituting the domestic well-todo, to support these policies because the distribution of incomes shifts noticeably in their favour, direct taxation rates on individuals and companies are reduced, subsidy cuts on food and the health and education sectors reduce workers' bargaining strength through a drastic reduction in the social wage, a profit inflation for business is ensured as necessities prices rise and real wages are restrained, and access to international consumption standards assured for the minority with the means as scarce foreign exchange is freed for consumer imports which were restricted earlier.

The domestic state, increasingly representing openly the interests of the well-to-do minority of its own population,

implements these policies because it finds it easier to borrow abroad than to tax the rich, and more expedient to pass the burden of deflation onto the poor than to impose discipline on its own profligate consumption (It is noteworthy that budgetary deflation does not even impose any real discipline on the budget since, as has been repeatedly pointed out by analysts, the government's revenue deficit continues to widen and the overall cut is achieved by slashing productive expenditures). The vision of 'national development' has been replaced by the economics of class expediency.

Some of the key influencers of decisionmaking in third world governments undergoing structural adjustment (and India is no exception in this respect) are themselves ex-employees of the IMF or IBRD, and can revert to these institutions, whose agenda they are implementing so faithfully, almost at any time they wish. They are as a faction of a class already 'globalised', and care little if the costs of imposing 'reforms' are borne by the mass of their countrymen who, unlike them, have access neither to dollar incomes nor to migration opportunities, their own 'safety nets' are already well in place, so that in the event of a collapse of the system they are administering, they can easily migrate to their metropolitan havens. This represents an entirely new phenomenon, when 'nationalism' and 'patriotism' for this class mean little and indeed are treated as laughably outmoded ideas.

All this is not an individuals-specific matter but reflects larger forces, indeed a new phase of world capitalism itself with the reemergence of the dominance of highly mobile international finance capital. These decisionmakers enjoy not merely the support but the virtual adulation of a section of the urban well-to-do in India, who similarly today have personal access to international travel and consumption standards through their own jobs, and through children and relatives settled abroad. Though a tiny fraction of the total population, perhaps less than half per cent or so, in absolute terms their number is large and their influence is much larger than their numbers; they are supporters and beneficiaries of the new policies, which are entrenching their interests further at the expense of their ordinary countrymen. They can now insulate themselves from their fellow-countrymen in oases of high lifestyle comparable with or even better than anything abroad (since local labour remains cheap). On present indications they have been prepared to support the imposition of mass income deflation (via food price inflation and cutting state investment), the maintenance through repeated devaluations of a low effective exchange rate beneficial for the advanced country importers, the dismantling of domestic food security, the producers and take the country towards an exerall scenario of rising debt, low growth and increasingly more skewed income distribution.

No advanced capitalist country today will countenance being caught in a scenario where all of them are simultaneously carrying out devaluations as well as deflations. The last ime this happened in the developed world was 65 years ago in the slide to the great inter-war depression. Country after country undertook deflation to remain on the Gold Standard; later, as the Gold Standard collapsed they undertook competitive devaluations in an attempt to capture a larger share of by then declining world trade. The end result of combining simultaneous (viz, across countries) deflations combined with similarly simultaneous devaluations was, to say the least, distressing, and is now the stuff of economic history [see for example Kindelberger, The World in Depression 1929-1939].

Third world countries today are being asked to do precisely this: to competitively deflate and competitively devalue. There is in fact a remarkable similarity between the pre-Keynesian, quite disastrous economic policies that finance ministers the world over followed in the late 1920s, and the Fund-guided programmes that the indebted third world countries are obliged to follow today. The main difference is that today these policies are advised for the developing countries alone.

Devaluation squeezes real wages while deflation accentuates unemployment. A combination of the two - which when undertaken competitively by many countries does not even achieve its putative aim has a severe impact upon the working masses. And yet indebted developing countries, with 2 per cent of the per head income of the developed world, are expected under the Fund-Bank package to cope with the burden of simultaneous deflation and simultaneous devaluation (Table 1 covering 78 countries in the 1980s shows that the intersection set of countries implementing both, was at least half the total number). There is a ruthless implacability about the agenda, which, we would argue, is owing to the need for releasing exports, especially from the primary sector at cheapening rates from developing countries, by reducing domestic demand and absorption of their own products by the mass of the population.

It might be argued that reducing growth rates in the developing world adversely affects markets in them for advanced countries' exports and is therefore against their interest in this respect. However it has to be remembered that rise in their per head income is not the only way that developing countries can absorb more imports; after

barriers, the eroding of the developing countries' domestic industrial sector by displacing its production, or deindustrialisation, performs the same function equally well from the viewpoint of international capital. That is the basic reason for the insistence of the advanced world on clauses of mandatory market access in the GATT 1994. Studies of a number of African economies undertaking adjustment in the 1980s, have reached the conclusion that significant deindustrialisation has occurred already.

Why should the reduction of demand and absorption of their own products by third world populations, be necessary at all, and of benefit to advanced countries? This is the question to which we try to put forward the answer in the next section with reference to the agricultural sector. The answer involves a rejection of the entire body of previous theorising, based on 'comparative advantage', involving today's tropical developing countries.

International Division of Labour and Logical Fallacy in Comparative Cost Theory

There is a fallacy of logic in using the theory of comparative costs to explain that pattern of international division of labour which involves the export of agricultural products by the tropical and sub-tropical countries and the import of manufactured goods from more advanced northern countries. The fallacy lies in the fact that relative costs cannot be defined at all. This argument is explained further below.

There is a fundamental if obvious difference between agriculture and manufacturing, the economic consequences of which are usually not taken into account. Manufactured goods whether cement, textiles or steel, can be produced anywhere in the world, on the basis of imported raw materials if these are not locally available; but crops are ineluctably specific to particular climatesoil complexes. The overwhelming bulk of the earth's bio-diversity in general and botanic diversity in particular, is concentrated in the earth's tropical and sub-tropical areas which include India, where high ambient tempertures ensure year-round plant growth. In northern countries there is only one single natural growing season, the range of crops is relatively limited, and artificially extending the growing season is a highly energyintensive and prohibitively expensive proposition.

No amount of capitalist innovations can alter the fact that under field conditions Yorkshire can never grow bananas, Bavaria can never grow sugarcane and New England can never grow coffee. With a vast expenditure of energy derived from the fossil

cultivation may enable growing them in tiny quantities as in a botanical garden; but commercial cultivation on any scale is out of the question and imports are mandatory, for these products are by now essential elements in northern consumption baskets.

Large countries like India cannot only grow all the typically tropical crops, but potentially if not actually every crop that grows in Yorkshire, Bavaria, or New England. In addition to the specifically tropical crops, the temperate-land summer crops, fruits and vegetables are also easily grown in winter in sub-tropical climates. Where topography is such as to provide land at varying elevations, a highly diversified product-mix is possible.

Tropical lands with their unique capacity to produce a large variety of crops, are not in unlimited supply. We might not conceptualise tropical cultivable land as a completely non-renewable resource as we do the fossil tuels, but it is definitely a resource whose 'supply' can only be augmented with the greatest difficulty. Lateral expansion of cultivable area is no longer easily possible as it was in the last century and can only take place by further forest destruction carrying long-term adverse effects on rainfall and survival of species. (In some Asian countries cultivable area is actually falling as commercial, industrial and residential construction grows). Making an existing acre'do the work of two or three by raising output per unit area, is thus the only rational alternative. Heavy investment in research and in irrigation is required however to raise the yields from existing cultivable area, and after the 'green revolution' of the 1960s in the cereals no new really big breakthrough is as yet in sight. It is still potentially toxic heavy chemical fertiliser application on irrigated land to non-lodging varieties which is the source of yield rise

Further, the present logic of Fund-guided contractionary programmes has led if anything not to increase, but to prolonged deceleration in investment in irrigation and in agriculture in most tropical developing countries. Certainly we know that in In-lia investment in agriculture has been declining from the partial liberalisation of the 1980s and the present phase of SAP has seen a continuation of the decline. In the absence of adequate investment tropical land becomes a resource in virtually fixed supply, implying that growth in one component like agriexports can only be at the cost of decline in domestically consumed output. We will return to the emerging inverse relation between agri-exports and domestic food supply below. This emerging inverse relation is indeed the single most important outcome of the liberalisation of agriculture, carrying for the poor.

The basic of obvious fact of the concentration of hotanic diversity in tropical regions has determined the world division of labour in agricultural production. Its historical origins lay, not in Ricardo's 'comparative advantage' (which is probably the cleverest rationalisation of national selfinterest ever put forward by an economist), but in the use of mercantile arms backed by state power to secure for European populations, access at the cheapest possible rates to tropical products. The fact that Britain could grow no cotton, did not prevent the cotton textile industry emerging as the leading sector of the Industrial Revolution; but this improbable development was only made possible by securing an elastic supply of colonial raw cotton under the mercantilist system of prohibiting textile manufactures in the colonies while pushing the cultivation of the raw material. The fact that Japan, that other island-nation on the edge of a continent, could grow little sugarcane itself, did not prevent the emergence of a large Japanese sugar refining industry; but this in turn was only possible by seizing and colonising subtropical Taiwan and developing sugarcane production.

The specialisation of Britain or Japan in manufacturing and their colonies in primary products, and the ensuing trade pattern, had nothing whatever to do with any Ricardian 'comparative cost advantage' or indeed 'absolute cost advantage'. There is a fundamental logical fallacy in trying to explain such specialisation using Ricardian theory. This theory (the standard twocountry, two-commodity model) is only applicable where both countries can produce both commodities; this is a necessary condition for calculating and comparing production costs. Tropical primary products are by definition not producible at all in temperate regions, so production cost sin-ply cannot be defined for these commodities for these regions; hence neither absolute nor relative costs are definable.

To say for example that Britain had a comparative advantage in textiles relative to India whose advantage lay in sugarcane (or jute, or tea), is a nonsensical proposition, for while the cost of both goods can be defined for India, sugarcane, jute or tea cannot be produced in Britain, hence its cost cannot be defined. If cost cannot be defined, cost ratios are undefinable. We can attempt a mathematical solution to the problem perhaps by assuming a fictional output of sugarcane (or jute or tea) in Britain and imputing an infinitely high cost of production to it. But this is not Ricardo's theory which assumes that both commodities are producible, and are actually produced in the pre-trade situation, in both countries: only on this

of both goods improves for each country through trade (in the sense of more of one good and no less of the other good, i e, vectorwise improvement). Fictional outputs have no place in Ricardo's theory because the vectorwise improvement in the availability of both commodities in both countries through trade is the explanation as well as the justification of trade in the comparative cost theory [see Samuelson 1965, pp 426-38 for a formal exposition of Ricardo which is based precisely on the production of both goods in both countries in the pre-trade situation].

On the other hand one might try to rescue the theory by interpreting the 'vectorwise improvement' to mean a Pareto improvement in utilities in each country rather than an improvement in the physical commodity bundles available in each, in the post-trade situation as compared to the pre-trade one. This is trying to arrive at a weaker version of Ricardo's conclusion about mutual benefit from trade, without making Ricardo's assumption (making use instead in the process, of fictional outputs with infinitely high costs of production); but this device too will not work. The conclusion about beneficial effects of trade even in this sense does not necessarily follow. Indeed for the tropical country trade becomes positively harmful: because of the inelastic supply of tropical land - in the absence of adequate investment which the market itself does not call forth – the export of tropical products would necessarily reduce domestic availability of such products or of foodgrains, and leave the mass of the population worse off, for which manufactured imports from the north, no matter how cheap, cannot compensate

The comparative cost theory thus breaks down for all trade involving tropical products viz-a-viv northern countries. Relative cost cannot be defined at all where some goods cannot be produced, and rescue efforts through virious logical stratagems like assuming fictional outputs and weakening the mututal benefit condition, do not work. This simple point which nevertheless constitutes a powerful logical critique of the common fallacy of invoking Ricardiantheory to explain international specialisation, has not been made before to our knowledge.

As a matter of fact, the criticism is applicable not only to the present use of Ricardo's theory; it is equally applicable to Ricardo', original example of specialisation in wine production by Portugal and in cloth production by England, which would occur if the relative cost of wine production was lower in the former. This is an example which finds a place in every economics textbook to this day and is uncritically taught the world over to students. This particular

as well since commercial large-scale grape production was not possible in England, located as it was in the northern part of Europe, owing to its cooler and more variable summers compared to the central and southern continental countries. The cool temperate lands generally cannot cultivate grapes. Since grapewine could not be produced its relative cost could not be defined. (The natural, genetically untampered grapevine or vitis could indeed perhaps be grown with great care though giving low yield, in England in a few very limited south-facing and wind-sheltered locations in Cornwall or in heated conservatories; but not on any scale under field conditions Incidentally it is amusing to note that Samuelson 1965, ibidem while providing a modern exposition of Ricardo's theory, quietly substitutes 'food' for 'wine' in the original two-commodity two-country model of Ricardo without mentioning why he does so. Food is of course producible in both countries while wine is not. It is possible that he smelt a rat in the original example but thought it best not to explore the issue, with its subversive implications for the 'mutual benefit' conclusion, any further)

Britain wanted a large supply of inexpensive grapewine to consume but could not produce it. The real reason for warmer Portugal obligingly exporting its low-value wine and giving access to its own markets for higher value cloth to Britain - resulting in the relative decline of its local cloth production, or deindustralisation - lay in its relationship of naval and diplomatic dependence, indeed near subjugation, to Britain both when Portugal was fighting Spanish rule over its population as well as later in the course of the war of the Spanish Succession Britain's naval ascendancy left Portugal with little choice in the matter of trade. Britain had even succeeded through a combination of naval bullying and diplomacy, in wresting from Portugal the coveted, highly lucrative Asiento or monopoly of supplying slaves to the Spanish empire in South America from Portuguese West Africa; and later obtained more trade concessions for its merchants located in Lisbon including the agreement on the exchange of cloth for wine [see Boxer 1969 and Hill 1966].

The central role of military violence, interestingly, drops out of the picture entirely once we come to the subsequent theorisation of the trade pattern by English political economists: Ricardo's illustration and explanation is entirely in terms of neutral, technologically given cost factors. The very fact of the emphasis on cost ratios serves to divert attention from the basic point of whether cost is at all definable; it acts as an intellectual sleight-of-hand. Without entering

unto the vector and perhaps unanswerable question of to what extent Ricardo was aware of what he was doing, as far as his theory is concerned it clearly played the role of rationalising – as being mutually beneficial and therefore voluntarily entered into by both sides – and thus intellectually justifying a trade pattern which in reality was to Britain's benefit and to the trading partner's detriment. The rationalisation was powerful because it was stated in terms of what looked like objective economic law, even though the real historical mechanism leading to that trade pattern as well as its welfare outcome were quite the contrary of that postulated.

The obfuscating power of the intellectual construct should be clear from the fact that every economics textbook uncritically carries to this day this logically incorrect illustration of Ricardian comparative advantage. Further, the theory is used systematically to suggest that the trade pattern historically imposed by armed force and economic coercion upon subjugated or colonised peoples by the west Europeans, resulted in a mutual advantageous specialisation. So successfully has the hegemonic theory suborned the capacity for independent logical thought that we find third world historians and economists themselves putting forward this fallacious argument, vide the invocation by K N Chaudhuri in the Cambridge Economic History of India 1985, of Ricardian comparative advantage as the explanation of India being reduced to importing Lancashire cloth and exporting primary sector products in the early 19th century.

During the last three centuries, the consumption basket of Europeans including those who emigrated and populated the temperate areas of the Americas, has been transformed: but only partly owing to improvements in their domestic agriculture. and very largely owing to increasing dependence on imported tropical and subtropical products which provided the physical basis for rising standards of living. Reliance on the products of their own agriculture had historically meant a very limited consumption basket for the Europeans. Late medieval temperate agriculture had a remarkably low productivity owing to a short growing season confined to a few summer months over much of Europe, a seed to yield percentage as high as 25 to 40, and the fact that only one-third to half of cultivable land at any given time could actually grow anything because fallowing to keep up soil fertility was necessary in the absence of adequate manuring 'van Bath 1963]. The inability to grow enough loodgrains for humans as well as fodder for inimals entailed mandatory livestock culling n the onset of winter and lowered the vailabilty of manures which in turn kept yields low and perpetuated the vicious circle. 1 atin Europeans however were somewhat better off and enjoyed the saving grace of the vine, the olive and some citrus fruit.

Analysing the data on the diet of serfs and lords on the feudal estates of Germany and Sweden in the 16th century, van Bath (1963) finds that the average diet provided more than adequate calories at about 3,500 to 4,000 per head but was grossly ill-balanced and monotonous, consisting of large quantities of bread, rancid salt butter, a little cheese, and meat of which only 10 per cent was fresh and 90 per cent preserved and heavily salted. Vegetables and fruit were limited to the few summer months; the highly saline diet generated an 'oceanic thirst' so that beer consumption per head was some 40 times higher than in present times. Herrings supplemented this diet for coastal peoples. Vitamin and other micronutrient deficiency diseases (rickets, night blindness, scurvy, etc), hypertension and cardiac disease must have been much more common than

By contrast, in the Ain-i-Akhari, part of the Akbarnama written by Abu'l Fazl Allami during emperor Akbar's reign in India in the late 16th century, we find a list, stated to be not exhaustive, of the market prices of 35 kinds of fruit and 26 kinds of vegetables (see Ain 27 and Ain 28, Akbarnama translated Blochmann 1887] Consumption may have been limited by income, but not by the inability to produce. Net yields of cereals per unit of arable land were substantially higher than in Europe owing to low fallowing, at least two growing seasons in the year, a low seed to yield percentage of around 10, and the ability to multiple-crop under irrigated conditions.

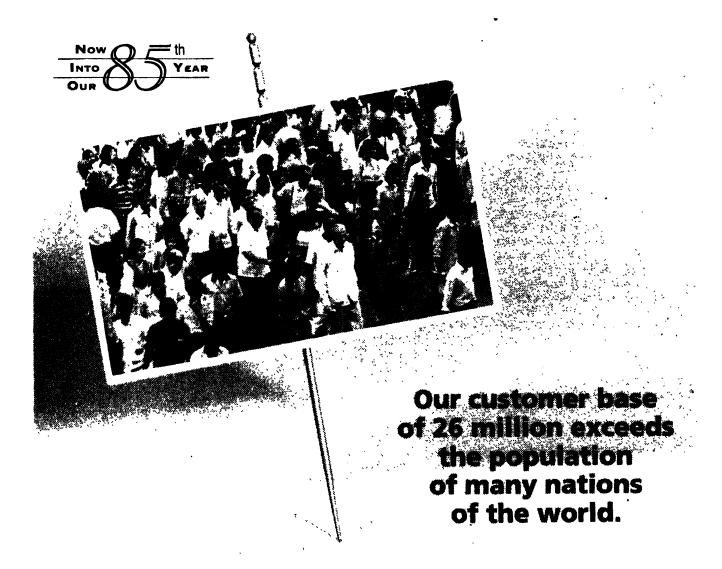

The improvements in European agriculture starting in England from the 18th century, involved root and leguminous fodder crops which permitted livestock to be fed through winter; convertible husbandry increased the supply of fresh meat and manures, breaking the late medieval vicious circle of very low productivity. The 'agricultural revolution' in Britain, the country with the most improvements, seems all the same rather unimpressive: Mingay tells us that grain output rose by 50 per cent at most during 1700 to 1850, which gives us an annual compound growth rate of only 0.27 per cent [Mingay 1967], which fell behind the estimated population growth rate by the mid-18th century Nevertheless the consumption basket of the British and other west Europeans through the 18th century was being transformed, and this was owing to the institution of mercantilist trade patterns following their seizure of the Americas, parts of Africa and the colonisation of Asia and the Caribbean. The greatest land and resource grab ever in the history of human societies by the Europeans, predates the rise of industrial capital.

With the seizure of tropical colonies, we know that Europeans proceeded with great energy to exploit for themselves the benefits of tropical botanic diversity, by dispersing a range of commercially valuable crops (sugarcane, rubber, cotton, tea, coffee and so on) from their countries of origin to colonies with similar climatic conditions, for plantation production for export to metropolitan markets. For this purpose they similarly trasported West Africans, kidnapped and enslaved, and later Asian indentured workers, thousands of miles to serve through their labour the interests of the new globalised capital, W. A. Lewis (1978) estimates that from the second half of the 19th century alone about 50 million Europeans migrated to settle and develop the resources of the temperate lands they seized, while a similar number of Africans and Asians, about 50 million, were transported by them as cheap slave and coolie labour to work the mines and plantations feeding metropolitan industry and consumption.

As the leading colonial power, Britain by 1830 already had tropical imports amounting to as high as 40 per cent of its own domestic production by value if we consider primary goods and by 1860 this had increased to a staggering 60 per cent [calculated from data in Mitchell and Deane's Abstract of British Historical Statistics 1966] These are underestimates given the method of valuation used in the statistics. A developing country today with even half this degree of impordependence would at once plunge into balance of payments crisis. External payments problems seldom troubled the European colonisers however, because with political control the tropical import surplus for them, became costless. It was financed by using a large part of the tax revenues obtained from the colonised people themselves to purchase the importables, the metropolitan import surplus of goods from the colonies thus represented a different economic category from an import surplus under normal trade. It was nothing but the transfer of the commodity equivalent of a part of the colonial tax revenues. As far as Britain was concerned on average over half its huge tropical import was re-exported to temperate countries (mainly Continental Europe) to pay for its imports from them, thus solving potentially serious payments problems given inclastic demand for British exportables

### INVERSE RELATION OF FOOD AVAILABILITY AND AGRI-EXPORTS

In the modern world the mechanism of taxation is replaced by that of the external debt of third world countries, whose servicing requires an export thrust and absorbs a

We have one of the largest customer bases in the Banking world.

And our satisfied customer base is larger than the population of many nations in the world - both developing and developed.

Incredible, isn't it? We serve our 26 million account holders through over 3000 branches. Our savings account holders, numbering over 15.6 million, constitute over 60 per cent of our total number of accounts.

Our response times are now even shorter with extensive computerisation.

The accelerated process of computerisation at the Bank's major branch network of metros and urban centres would cover around 40 percent of the Bank's business.

We have introduced several new customer oriented, customer friendly schemes. Like the Quick Cheque Collection (QCC) facility.

Specialised branches for sophisticated needs of Industrial and Overseas Business. Designated branches to handle Housing Finance, Hi-tech Agriculture Finance and SSIs. And many more.

And, with our improved customer-friendly thrust, we added over one million account holders.

At Central Bank, the central focus is commitment to service.

substantial part of their export earnings. The heaviness of debt in third world countries is partly the result of their attempt to develop today in a much more hostile world dominated by the early industrialisers and with no access to large transfers such as those advanced nations historically enjoyed from today's developing countries. The heaviness of debt is also the outcome of the developing countries not being paid enough for their exports compared to their imports, and continuous pressure on them to cheapen their exports further.

The reason for dwelling on the mechanism of tax-financed exports in colonial times, is to stress the fact that it necessarily operated via a domestic deflation. If a part of budgetary revenues is set aside every year in the colony for paying local exportable producers and the foreign exchange earned by the export surplus does not accrue to the producers but is diverted to metropolitan use, then this is equivalent to the following scenario: a surplus budget is being operated (the surplus being equal to the magnitude of the transfer abroad) to reduce domestic demand, and the commodities so released are then bought up using the unspent revenue and taken out as unrequited exports (for the modus operandi of colonial fiscal policy see S Sen, Colonies and Empire, 1992). Income deflation was a necessary economic mechanism from the rulers' viewpoint because the rate of growth of Indians' income had to be limited in order to keep in check their market demand for domestically consumed goods, and thus divert a larger part of available limited resources especially irrigated land, away from these domestically consumed goods to the production of the tropical primary exports needed by the industrialising powers.

The most important domestically consumed necessity was foodgrains, and its growth necesarily declined to accommodate the growth of exported crops. 'Necessarily' is used here in a contingent sense; had the colonial government pumped large enough investment into irrigation, improved seeds and fertilisers in order to raise grain productivity, then food output could perhaps have been maintained even with increasing agri-exports. But no colonial government's priority was to see that the average local producer continued to eat at least the same amount of food as before commercialisation. Its priority was to secure a cheap and elastic supply of the commercial tropical raw materials which fed its home industry and the tropical consumption goods which had tecome a part of the the essential consumption basket of the home population or which could be exchanged for imports from other temperate land countries.

We extend the argument to present times; as in the past, there is a basic asymmetry which continues to exist with respect to

global agriculture. Every developed northern country continues to make systematic and ever larger demands on the limited productive capacity of tropical and sub-tropical lands, while the converse is not true: the populations of developing countries have neither historically made demands on temperate lands, nor do they wish today to become wheat importers from them. They are perfectly capable of meeting their own food requirements if they were left alone to do so and were not called upon to meet the demands of northern countries which are habituated by now to consume a huge range of products only producible in Southern lands. With no access to tropical colonies other than the Philippines for any length of time, the US too has developed a highly import-dependent consumption pattern ensured by the contractual control exercised by its transnational food companies on third world producers.

In this context it will be worth bearing in mind that strawberries in July and strawberries in January are analytically two 'different' crops, most of Europe or north America can produce the former but not the latter; so northern demand is by no means confined to typically tropical crops like sugarcane or coffee, but includes all crops which are seasonally limited in temperate lands but are easily producible in winter in countries like ours. Hence the thrust by the TNCs in the global food business is to displace third world iand already under foodcrops, to those vegetables and fruits which will iron out seasonal imbalance of supply for northern populations. Fresh, frozen and canned vegetables and fruits are cheaply available all the year round to consumers in western Europe and north America, whereas consumption patterns to this day in east Europe or Russia which never colonised or exploited the third world, are much less diversified, more 'primitive', seasonally constrained and local productsdependent.

It is not the priority of any advanced country today, to ensure that the demands it makes on tropical agriculture are consistent with local populations retaining enough to eat themselves. True, the advanced countries strenuously push wheat exports to them; but since the price of tropical exportables are under continuous downward pressure, terms of trade tend to turn against the developing world reducing its ability to import food and forcing consumption decline. In fact we already find, in the countries with the most successful agri-exports drive, severe decline in per head food production and since food imports usually cannot be increased enough to compensate owing to declining international terms of trade, there is also a decline in availability and a rise in the numbers of the famine-vulnerable. Some data from sub-Saharan Africa are examined later. It is evident from a study of history that the cost of ensuring a cheap stream of agri-exports to the metropoles was very high for the colonised populations: no less than a substantial decline in their own absorption of basic foodgrams, a decline in their level of nutrition. In India for example, exportable commercial crops giew more than 10 times faster at 1.31 per cent annually compared to only 0.11 per cent per annum for the foodgrains over the period 1894 to 1947 according to G Blyn's estimate for British India. The per head exportables production rose, but the production and availability per head of foodgrains declined by 25 per cent overall for British India in the inter-war period. The decline was highest in Bengal, Bihar and Orissa at 38 per cent while even the most dynamic region, Punjab saw an 18 per cent decline [see Blyn 1966]. We have elsewhere argued [see Patnaik 1991] that this secular fall in food availability, combined with the adverse movement in the international terms of trade for primary products, created the preconditions for famine. Traditional systems of food security were continuously undermined by exports and the inter-war decline in terms of trade in a completely open, liberalised economy, sharply increased the numbers of faminevulnerable. Any shock to the system could then set off actual famine, as indeed happened in Bengal in 1913-44.

The scenario of falling nutrition levels for the colonised as a direct result of exports to the metropole, was a general one Japan, during the relatively short periods that it colonised Korea and Taiwan (1910 to 1945 and 1895 to 1945) developed these areas vigorously as suppliers of rice and sugarcane Despite the fact that it pumped in a good deal more of investment to ensure high growth than Britain had done in India, in Korea so large was the increase in exports of rice (rising from less than 1 per cent to 65 per cent of increasing rice imports into Japan during 1897 to 1937) that consumption of foodgrains by the Koreans fell [see Grabowski 1986] Inferior millet from Manchuria substituted for rice in the colonised Koreans' diet, but the calorie content of the average diet is estimated to have declined by 18 per cent over the two decades before the second war. The poorer peasants were reduced to eating wild grasses and tubers for two to three months in the year [see Hayami and Ruttan 1970]

We put forward the proposition here that the real as opposed to the putative rationale of imposing income deflation on all indebted third world countries today by the Fund-Bank, is no different from the rationale in colonial times. Given inadequate growth of production the only way that more exports can be squeezed out at low prices is through The rare flavour of 100% pure Darjeeling tea

The Gentle Art of Living Well

**Brooke Bond Lipton India Limited** 

limiting the absorption of their own products by the third world populations. Mass income deflation does not correct long-run payments imbalance when accompanied by trade liberalisation and more skewed incomes over social classes, as the experience of dozens of adjusting countries amply demonstrates; but it does serve as a very effective economic mechanism for reducing the growth rate of third world consumption and releasing exports (which are either only producible in these countries or are producible at much lower cost than elsewhere). Now as then, the maintenance of the developed world's high living standards is crucially dependent on a cheap and elastic supply of imports from developing countries; we would argue also below, that there are recent shifts in consumption patterns which are resulting in fresh demands on the limited productive capacity of fragile tropical and sub-tropical lands.

The structural characteristics of the colonial syndrome in the agrarian sphere - the growth of exports and decline in the absorption of basic food staples by the poorer majority of local populations – is being replicated today all over the developing world as a general trend which is sharply accelerated in the countries following trade liberalisation and SAP. It is important to remember, and it will bear repeating, that the regime of primary sector export drive in every third world country undertaking liberalisation and SAP today, is also the regime of mand story macroeconomic contraction, and hence of decline in rates of productive investment and growth including in agriculture. There is thus not the remotest possibility of combining high agri-exportables growth with high growth of domestically consumed crops.

Where investment rates are falling, increasing exports can only take place by reducing domestic absorption. Income deflating policies thus are the 'necessary' mechanism to lower domestic absorption of basic foodgrains and other necessities, divert scarce tropical land and investment to agriexports which are pushed strenuously by state policies. Rising export volumes are squeezed out at falling prices as more and more developing countries are required to follow the same policies and compete against each other to export similar products. What we are witnessing today is the economic recolonisation of third world agriculture, but under less transparent and hence more effective forms of subversion of their national food security. It is a subversion which is aided and abetted by a section of the governing elites in these countries which have been intellectually suborned by powerful ideological constructs (including modern use of the logically incorrect theory of comparative advantage) and materially suborned by being given access to international living standard provided they help to immiserise their countrymen.

Contraction in economic activity continues to be the unchanged Fund-Bank putative recipe for 'adjustment' although it is not a necessary condition for achieving the declared aim of external and internal balance. and it is zealously implemented in every case. Because in fact it has been highly successful in squeezing out third world exports at declining prices, to the great benefit of the developed world, and also highly successful in tilting income distribution further in favour of the third world rich, we believe it is going to continue to be implemented regardless of how much evidence is compiled (including by individuals employed by these organisations) of the extremely adverse effects on poverty, food security, health and education levels in the exporting countries. No change in the highly successful basic agenda can be expected. We can expect, rather, more programmes to limit the most distressing manifestations of incomereducing policies.

The reasons for the international lending agencies, talking a great deal about the need for poverty reduction and of 'safety-nets' even though it is the deflationary, mass income contracting policies administered under the close guidance of these agencies which in fact increase poverty - lie in their tear of the outcomes of possible passive revolt through migration of a section of third world producers and of widespread sociopolitical upheaval. To consider the colonial analogy, it was certainly not in the long-term interests of the British in India that peasants should be over-exploited to the extent that they died off in such vast numbers in famines induced by colonial policies themselves, as to adversely affect total taxable incomes; for that would amount to killing the goose that laid the golden eggs. What might be called a 'sustainable rate of exploitation' was thus a rational desideratum, and famines had to be contained and limited at the same time as the basic policies leading to famines, continued to be followed.

It is similarly certainly not in the interests of the advanced world today that the exploitation of the third world should be so excessive as to affect the political stability of the existing international order (although infact we see this outcome in some individual cases, where amongst other factors, Fund-Bank induced economic crisis has helped to catalyse social disintegration via ethnic and communal strife; Sri Lanka is an example).

An important consideration underlying the anxiety to contain poverty, is the present contradiction between the complete international mobility of goods and capital which is demanded and substantially obtained by the advanced countries, and their insistent sabotaging of the complete international mobility of labour, through the imposition of restrictions on immigration of unskilled labour from developing countries. The advocates of liberalisation, are both inconsistent and hypocritical in that they want the full liberalisation of goods and speculative capital movement from their own countries to the developing world (and indeed this is part of loan-conditionalities), but they wish to regulate strictly the inflow into their own countries, of third world labour displaced from their occupations owing precisely to the de-industrialisation induced by the unregulated inflow of goods into these countries and the winding up of their public enterprises.

However, there are limits to control: as more third world producers are displaced or marginalised they will take higher risks to migrate illegally to advanced high-wage countries which in turn will have to devote more resources to keep them out, or face the rise of domestic fascist organisations, which are indeed already gaining strength on the European continent largely on an unemployment and anti-immigrant platform. Given such a scenario it becomes important to advanced countries to ensure that at the same time that the exploitation of the third world continues, poverty there is sufficiently contained through various schemes as to induce the bulk of the unemployed and destitute to stay put in their own countries, even as the movement of capital and goods is fully internationalised

CHANGING PAITERN OF ADVANCED COUNTRIES' DEMAND ON FRAGILE TROPICAL AGRICULTURAL PRODUCTIVE CAPACITY

The high living standards of western European and north American populations today depend crucially on the availability of an uninterrupted, elastic supply of cheap energy on the one hand, and of a large range of imported goods from tropical and subtropical countries on the other hand. Ensuring the continuing cheapness of these two crucial factors underpinning living standards, has been probably more important than ever before as the recession which started in the 1980s continues in most advanced countries and so do fairly high unemployment rates. This in turn, it has been argued, has to do with the new phase of dominance of finance capital which ensures its international mobility in search of speculative profits, to the detriment of productive investment and growth in real sectors [P Patnaik 1993]. The advanced countries have had some of the lowest per capita annual growth rates in the world in the last 15 years, falling to negative rates in many years and seldom exceeding I per cent when positive; this period has also seen a dramatic increase in the rates of surplus value in these countries, and yet real maintained, but have risen for substantial sections owing to the remarkable price stability they have ensured, to which the steady fall in imported primary products prices have contributed substantially.

We know that each north American uses up over 8,000 units of oil-equivalent of commercial energy every year compared to over 5,500 units in western Europe and 3,600 units in Japan, while India's per head energy consumption is only around 220 units and China's is less than 600 units (these orders of magnitude were quoted during the Earth Summit in 1992). These are very roughly proportional to the respective per head incomes. Thus, India's per capita energy use is only one-fortieth and one-twentyfifth of the north American and European levels, China's being one-fourteenth and one-ninth respectively. This implies a very high degree of skewness in global energy consumption, most of which is derived from the fossil fuels. With barely 5 per cent of world population, north America alone accounts for a third of world energy consumption, while at the other extreme with nearly 38 per cent of world population, India and China account for only 12 per cent of global energy consumption.

There is a great deal of talk about the developing countries especially India and China being overpopulated. The relevant concept here however is not the nominal population but the standardised or real population, where the basis of standardisation is an index derived from the per head demand on non-renewable resources, for which the energy demand can serve as a proxy. Taking the Chinese per head energy use as the base of such a simple index, China's nominal and real population would be identical at 1200 million, or 1.2 billion. India's real population works out to 0.33 billion, while north America has a real population of as much as 4.1 billion; western Europe and Japan together would contribute at least another 2.9 billion. Thus, the advanced countries represent a real population of 7 billion compared to the mere 1.53 billion real population of the two most nominally populous countries in the world.

A similar order of drain on the fragile productive capacity of tropical and subtropical lands is imposed by the northern countries owing to their high incomes, and hence their high 'effective populations', as on world energy resources the bulk of which is derived from the fossil fuels. Tropical and sub-tropical land may not be an entirely exhaustible resource like the fossil fuels, but as earlier argued it is in practice in sufficiently inelastic supply for a serious problem to arise for the mass of third world populations when there is rise and diversification of consumption by the metropolitan centres

income. They demand complete opening up of the agricultural sector of developing countries because this will allow the powerful magnet of advanced countries' effective demand to restructure third world crop production to their own requirements.

Every northern household today is habituated to consuming daily a large range of products imported from tropical and subtropical countries, which cannot moreover in the main be 'import- substituted' domestically except for a few items where synthetic or other substitutes have been developed (e g, synthetic vanilla flavour, high-fructose corn syrup replacing sugar in some uses): but without ever completely displacing the premium market for 'the real thing'. From the moment of awakening in the morning to retiring at night the typical consumer's high standard of life is underpinned by a plentiful and cheap availability of imported products. Beverages like coffee, tea, cocoa, and fruit juices; vegetables and fruits in fresh, frozen or canned forms; vegetable oils in liquid and hydrogenated forms; cane sugar and flowerspecific honeys; lean meat; fish and seafood; cocoa and sugar-based chocolates, syrups, ice-cream and confectionery; spices and flavourings; tropical cereals, nuts, sugarbased alcoholic beverages and tobacco; salt; flowers and ornamental plants comprise some of the large range of imported items in daily

Other tropical products are essential elements in the pharmaceutical and cosmetics industries. In textiles, cottons and fibres that 'breathe' owing to the admixture of cotton are increasingly preferred to pure synthetics. The imported vegetables and fruit are not confined to tropical varieties alone; equally important is the evening out of otherwise large seasonal supply variation through the import of northern summer varieties in their barren winter season. The TNCs engaged in agri-business operate in an oligopolistically highly competitive world; where debtconditionalities prise open fresh lands in developing countries suitable for potentially lower-cost production, they move in fast and often demand reverse land reform such as the lifting of restrictions on maximum farm size. Where direct control over land is difficult the TNCs have worked out forms of contractual control over local producers who are offered initially attractive terms. Often consumer tastes in advanced markets are created by the very operation of the TNCs, and new products (such as kiwi-fruit) are constantly added. Diversification has been aided by the marked spread of healthconsciousness within the general mass of northern populations.

A typical northern supermarket say in the US at present carries on average about 12,000

[Friedman 1990]. Many foods are available in several presentations (for example in sugar, from regular granulated to caster and varieties of brown and demerara). Speciality shops or special counters in supermarkets provide exotic foods from every part of the world. A quick survey will indicate that at least three-fifths of all food items on display in a supermarket are wholly or partly tropical to sub-tropical in origin; for ethnic supermarkets the proportion would be even higher.

To an observer from a developing country like India where import dependence for items of direct food consumption is nearly zero, such a high degree of physical import dependence of northern populations is a very striking phenomenon. If for some reason the supply of these commodities was to dry up and they were to disappear entirely from the supermarket shelves, leaving locally available temperate land goods alone, then the high living standards to which west Europeans and North Americans are habituated would drop sharply. They would drop, if not to near-medieval levels, then at least to the levels still prevalent in the east European countries, which are viewed contemptuously by west Europeans. The east Europeans historically never enslaved or colonised anybody, thus had no cheap access to tropical lands, and continue to have much more 'primitive' and hardly diversified local-products dependent consumption

The reader should not imagine that our argument is limited to a purely 'geographical' one or necessarily requires the absolute inability to produce a particular good by the northern country. The natural monopoly of botanic diversity in the third world countries continues to be of very great importance, but it is the limiting case of a general situation where as long as northern demand cannot be satisfied by local northern production, there will be pressure on the inelastic supply of third world land. Thus, if we consider a large country like the US which itself contains some sub-tropical areas in its southernmost states capable of growing crops like sugarcane or pineapple, we find that it nevertheless imports these commodities on a large scale, for local production can only satisfy a fraction of national demand and the crops are producible more cheaply abroad in low-wage economies. Similarly the typical temperate land fruits and vegetables other than the highly perishable ones are also profitably imported by TNCs from countries where their seasonal spread is larger and where they are often producible at a lower cost than in the temperate countries themselves, ensuring larger profits for the TNCs. That such trade is of benefit to northern countries can hardly be doubted; but the benefit to the developing country promoting agri-exports can be negative insofar as there is diversion there of land and investment away from domestically consumed goods whose availability falls.

It will not do to argue that these products imported from developing countries today make up a small fraction of total consumer expenditure in advanced countries or that raw materials and minerals are a small fraction of value added in industry, and that they are therefore unimportant. What is important is their ubiquitous physical presence in northern life-styles. One may as well argue that the air we breathe is not important because it appears to bear a zero fraction to our income.

Our argument is precisely that primary imports from tropical regions are bound to be a small proportion by value of northern incomes because they are obtained on such favourable price terms by the importers. They have very high use-value but are assigned a relatively low exchange value by the international market, which can be viewed as the expression of a historically structured set of power relations. Another way of saying the same thing is that northern living standards are high at least partly because the prices paid to the third world producers for a range of imported goods which by now are taken for granted as necessities, are so low: and are deliberately lowered further through the imposition of a specific set of loan-conditional policies (more crosscountry simultaneity of competing export thrust, more similarly competitive devaluation).

International prices for primary products do not reflect today, any more than they did earlier, the cost to the third world societies supplying them. The cost has been, and is very high; at best, there is a slow long-term trend of lowering of basic food consumption and of nutrition levels for the poorest sections of the population which may be the majority: at worst, where the initial levels of food consumption were low to begin with, there is the creation of pre-famine conditions as resources are diverted to exports, and outbreak of actual famine can then occur with any economic shock. Much of sub-Saharan Africa has already reached the second stage. The solution advocated by world lending agencies for their crisis, predictably, continues to be more income reducing and poverty creating policies: more export promotion, more 'fiscal discipline' and more devaluation.

There are quite noticeable shifts in consumer tastes among metropolitan populations which we would argue, on balance have been increasing their demands made on tropical agriculture, and which underlie the new thrust to obtain cheap importables. These shifts in the pattern of consumer demand are partly the function of

rising real income and partly the outcome of increasing health consciousness and knowledge of what constitutes a healthy diet and life-style, which from being the preserve of a few people considered eccentric earlier, has been spreading rapidly amongst the general population during the last decade in particular. Environmental consciousness has also increased greatly and the 'green' movement has had an appreciable impact on peoples' perception of organically grown food, free of artificial preservatives and colourings, as more healthy; this in turn has profitability implications in capitalist societies.

Prone to cardiac disease, cancers and digestive tract disorders, the illnesses of affluence, consumers in advanced countries are, under medical advice, cutting down relatively on fats especially of animal origin (lard and butter) as a cooking medium and shifting to vegetable oils. They are also shifting from fatty meat to lean meat, fish and sea-food; they are urged to include less carbohydrate per se and more fibre and vitamins in their diet which traditionally is based on over-refined, excessively starchy and fatty foods. To this end there is higher demand for whole grain cereals, green vegetables, fruit and other sources of fibre. Words like 'cholesterol' and 'monounsaturated oils' are today part of every educated person's vocabulary, including the well-to-do in the third world countries themselves. Food processing companies bombard consumers with valid and spurious health claims for their products.

Only a fraction of the increased demand for vegetable oils, fruits, vegetables and fibre can be met from increased local production in cool temperate lands; the main local adaptations have been to reduce the refining of a part of wheat and other cereals to retain more protein and fibre, produce more whole-grain bread and increase citrus fruit output, most of which comes from the US. The bulk of the new demand for vegetable oils, fruits and vegetables however is expressing itself as a new onslaught on the limited productive capacity of tropical to sub-tropical lands. Hence the new round of relentless pressure on them to 'open up' their agriculture and engage once more in an agriexport drive as they were obliged to do in colonial times.

It would be misleading to expect any absolute decline in the consumption levels of high-fat milk, butter cheese, etc, or even of meat in the advanced countries. On the contrary we find that there has been a large rise in their levels from austere war conditions, in the course of the long postwar European economic boom. Japan is also seeing a marked shift in consumption patterns as new generations favour a more 'western' diet model based on milk and meat products,

as indeed are the younger generation of the well-to-do elites in the developing countries. However within a rising trend of animal protein consumption, relative shifts are taking place influenced by health consciousness. The use of lard (hog fat) and butter for cooking was widespread in Europe three decades ago; it is being partly replaced and partly supplemented by vegetable oils; this is reflected in the spurt in sunflower and safflower production, replacing foodgrains especially millets, in third world countries including India, under the aegis of the TNCs engaged in agri-exports.

The per head consumption of meat has increased greatly in the course of the long post-war economic boom in Europe. The shift to lean meat from fatty meat within a rising demand trend, has necessarily involved via the activities of the transnationals, a relocation of animal-production on the hoof to warm countries. Since fat is nature's protection to animals against cold, by definition lean animals cannot be raised in cold countries easily unless they spend their . lives in heated houses; genetic engineering to breed low-fat animals does not fully solve the problem of the expense of housing them. Hence the rapid relocation of beef production on the hoof to warmer countries: this has gone very far in countries like Mexico and El Salvador, displacing human foodgrains by animal fodder for feeding exported livestock, and with a lag a similar process is underway in many other developing countries including India.

Increased production of fish and sea-food for export is not as innocuous as it sounds, prawn culture for export is currently in the process of destroying paddy land through salination and creating unemployment in India as it already has in Thailand. As the North Atlantic and Sea of Japan fish yields are currently dropping sharply owing to over-exploitation, the industrial countries demand access to the Indian Ocean, among other rich and under-exploited seas; the entry of the giant mechanised foreign owned fishing fleets displaces local fishing communities and begins to step up the rate of depletion of marine resources to nigh levels.

The TNCs also displace area under foodgrains by contracting for the production f a range of fruits and vegetables destined for northern supermarket shelves in fresh, frozen or canned forms. In India the promotion of such agri-exports has been declared an official priority area, and a larger share of falling resources are to be devoted to this.

If the north lacks bio-diversity, it lacks neither overwhelming superiority in money power for funding research nor the will to appropriate the very genetic basis of this biodiversity for developing and patenting a

applications for the advanced world in the areas of pesticides, foods, cosmetics and medicines. As the long-term adverse toxic effects become known of using synthetic chemical pesticides and weedicides, fertilisers, food flavours, preservatives, dyes and cosmetics; and the adverse side-effects of many essential drugs become clearer, there is now a premium on biological pest control, organic fertiliser, use of natural, safer vegetable sources of sweeteners, preservatives, flavours, dyes, and herbal cosmetics; and on exploring new organic sources of safe and effective drugs for treating disease. For international corporations operating out of the advanced countries there is a potential market estimated to run into nearly a trillion dollars from these applications.

All this involves a fresh onslaught by them on tropical bio-diversity; for the overwhelming bulk of the basic plant and animal resources, including microorganisms, which can provide the genetic material for these new research applications, are physically located in the developing countries. Particularly rich are the tropical rain torests, special isolated bio-niches like the Malagasay, and the sub-Himalayan ecosystems. Northern scientists closely associated with industry are already in the process of recording the traditional medical knowledge of local communities, searching for, locating and removing for research the plants, roots and other organisms used in traditional systems - all without any compensation whatever to these communities or countries. It should be noted that advanced countries have a very strong system of individual and other forms of property, but no norms are followed when it comes to physical removal of the bio-resources of developing countries. A pittance may be paid to the simple tribal people whose knowledge is appropriated and who are used to guide the northern 'ethno-botanists' to the location of the local-rare plants and organisms, local scientists can often be manipulated for similarly minute individual sums and rewards to surrender knowledge of potential importance to the developing nation.

The substance of the new 'trade related intellectual property rights' or TRIPS regime of the GATT 1994 agreement as applied to agriculture, is to ignore completely the natural monopoly of bio-diversity that the third world has, by making no provision for compensating them for the use of these products. (The International Biodiversity Convention on the other hand remains a statement of pious intentions with no teeth for enforcing the property rights of local peoples). The TRIPS provisions in agriculture make mandatory new rules of

namely, that of research funds. Existing Patents Acts in signatory countries are required to be amended in order to include product patents in all spheres (medicines and agriculture had been earlier excluded) in addition to already existing process patents, and to increase the period of patent (doubling it from seven to 14 years in the Indian case). Given the fact that only 1 per cent of all patents are filed from developing countries, the disproportionate gains likely to be derived by foreign transnationals and governments monopolising research funding, is clear.

The new patent regime relating to agriculture initiated under GATT 1994 pointedly ignores the fact that the overwhelming bulk of genetic materials have been in the past and continue to be today, stolen from the developing countries by advanced countries' corporations and scientists, without any payment whatsoever for the natural monopoly that these countries have; it concentrates instead effectively, on legitimising this filching by allowing those who do it to file patents on products obtained from these genetic materials and enjoy rent from the higher prices that can be charged once a monopoly is granted.

#### FOOD SECURITY

Returning to the question of food security, let us briefly review the experience of Mexico and of the sub-Saharan African countries first, in 'successfully' engaging in an export thrust of such dimensions as to undermine their own food security and plunge substantial sections of their populations into a spiral of declining basic food consumption.

In Mexico which had pioneered the highyielding wheat varieties and had achieved a green revolution in the 1960s, food selfsufficiency was lost by the early 1970s, as under debt-induced liberalisation a massive new agri-exports thrust was initiated. displacing foodgrains relative to exportables and turning the northern provinces of the country virtually into an enclave tied to the US market. Despite the vastly increased agri-exports however, interestingly the agricultural sector in Mexico became a net loser of foreign exchange from 1974, as imports of foodgrains (wheat, maize and beans) had to be stepped up greatly. This was aggravated by the trend of absolute fall in prices since 1979 for tropical exportables relative to constant or slowly rising price of wheat and maize exported by the developed countries (Canada, the US, and of late the EEC).

The 'metropolitan demand', as it should be defined, comprises two segments: first, the Mexican rich, whose share of national income has been rising from already high levels and who spend a higher share of their food budget on animal foods; and the US whose impact has altered cropping patterns and land use in Mexico dramatically in a matter of two decades. The US demand comprises lean meat on the one hand and a range of fresh and frozen fruits and vegetables on the other: both together have displaced the output of maize and beans, the staples produced by the small-scale peasants whose economy has been caught in a spiral of deterioration as official price policy and investment priorities have favoured the new exportables (a trend little affected by the brief Lopez-Portillo interlude of privileging food during 1980-82). The exportables are grown by farmers under contract to the US -based transnational giants of the food industry, such as Birdseye/General Foods, Pet Inc, Del Monte, Gerber, Clement Jacques, etc, and live cattle supply is controlled by Ralston-Purina, Anderson-Clayton, Ciba-Geigy and others. This has ensured a growing supply at low prices of fruits and vegetables to US and western European supermarket shelves, and meat for the fast-food industry.

While the 'new exportables' growth spurted, the production of maize stagnated at only 0.7 per cent per year and beans output fell at -1.5 per cent annually between 1965-67 and 1976-78; their output per head of the Mexican population thus declined, as did the incomes of farmers in the subsistence sector. The traditional cash crops like sugarcane and cotton also declined as the new exportables increased. Many thousands of small farmers were forced to leave farming altogether and migrate in search of wagepaid work, swelling the army of the urban poor. Some of the displaced peasants succeed in running the gauntlet of the armed antiimmigration groups patrolling the US-Mexico border, and swell the army of illegal entrants into California, offering themselves for hire at five dollars a day as against the minimum wage of 40 dollars. No other developing country, however, has the benefit of a common border with the US: the labourers in India currently being displaced by the agri-export activities of the local capitalists and the TNC's unlike Mexican peasants have little hope of emigrating anywhere.

The Mexican case illustrates the competition between foodgrains and feedgrains, reminiscent of medieval Europe, which has resurfaced in the third world but with the scales tilted decisively in favour of feedgrains, because there is a high income elasticity of demand for meat among middle income metropolitan consumers, and it is their superior purchasing power which bids away land and resources from the basic grain staples consumed by the poor (Yotopoulos 1985). Cattle raised on Mexican ranches are fed according to a strict regimen prescribed by the TNC's engaged in supplying beef for

the US groundoest and processed rood industry. The growth rate of sorghum which is used as animal feed, has averaged 10.6 per cent annually over more than a decade ending in the triennium 1976-78 (see Table 5) and has risen further giving an annual rate of 13 per cent during 1970 to 1980, the highest for all crops. The proportion of total cultivated area under fodder crops, mainly sorghum, rose from 6 per cent to as much as 23 per cent and the share of grain output ted to livestock went up from 5 per cent to 32 per cent in the course of the two decades ending in 1980 [Rodrigues 1990].

Sorghum or jowar is at present a human foodgrain in India, grown and consumed by the labourers and small farmers in the lowrainfall areas of the country. Learning from the Mexican story, clearly any decline which is likely to be taking place in food availability for humans cannot be measured by looking at simple grain production data alone but requires also looking at the end-use of grain, namely what share of it is going into animal feed particularly for export either as feed itself or converted to meat. [The substitution of meat for cereals and pulses in dicts is known to be a highly land-using phenomenon, since the most efficient-practice meat production from large animals requires on average about 8 hectares of land for producing a mere quintal of meat (a part of this being pasture and the rest arable: see Bernstein et al 1990).] The displacement of human foodgrains can be very fast, as in Mexico, once a rapid growth of meat export starts for metropolitan consumption. The similarly devastating effects of cattle tanching for export in El Salvador have been well documented by now.

In India this process has already started quietly with livestock production growing last, in response first to urban demand from the well-to-do leading to a 45 per cent rise by 1989-90 over the 1981 base; and since the export promotion drive from 1991 it has accelerated with the Gulf countries providing the main market for meat exports so far, so that total livestock product index has been rising at an annual rate more than double that of the foodgrains. Apart from direct meat exports there is a fast growth of the output and export of high-concentrate soya cakes used as animal feed; the expansion of soya-bean has been displacing the coarse grains, in the peninsular states of India (Madhya Pradesh in particular), as we will

There is an important logical corollary from this trend of what the Latin American economists have long called 'ganaderizacion' or increasingly livestock-oriented production, as domestic income distribution worsens and liberalisation subjects the "conomy to the powerful pull of richer ountries' demand patterns. The corollary

is trial the rood availability decline for human consumption is likely to be greater than the official figures indicate.

The official Indian practice (cf the annual Economic Survey) which has been followed for over 40 years, is to calculate 'food availability' by simply deducting a standard fraction (at present one-eighth) for seed and feed from gross foodgrains output. This is already out of date, for it does not take account of the accelerating trend of livestock production and its growing draft on grains for feed. Researchers need to estimate what precisely is the fraction of grain output actually remaining for domestic human consumption, before any complacent statements are made regarding the adequacy of availability for the 80 per cent of the Indian population which cannot afford anything but the basic staples. The official 'food availability' figures in grams per head per day which are widely used, no longer reflect actual availability for human populations.

The fact of the decline of per head food production in sub-Saharan Africa is well known, but what is usually neither perceived nor discussed, is its direct association with the successful drive for agri-exports. Looking at food output decline first, the calculations in UN publications (such as African Development Indicators 1992) are idiosyncratic in including palm-oil and sugarcane in 'food crops' whereas these are in fact commercial non-food crops. We adopt a more logical definition of food crops to include cereals, potatoes and other tubers, plantains and bananas; noting that although in Asia only cereals out of these are included in foodgrains, the importance of tubers and plantains as a food staple in many African countries make their inclusion mandatory. This definition of output is not the same as output available for local human consumption, as some part of bananas are in fact exported, some part of cassava used for commercial starch production, and some part of grain is used for livestock feed for export. This overstatement makes the test for our argument of decline in domestic food production affecting human consumption levels, a more stringent one.

It is the convention in countries with a large potato output like China, to aggregate tubers and grain by using the conversion rate 5 kg tubers = 1 kg grain. We follow the same convention in the table below for tubers as well as plantains in calculating total food output.

The six most populous countries (Nigeria. Ethiopia, Sudan, Kenya, Tanzania and Zaire) accounted for nearly three-fifths of the total population of the region. From our estimates above it is clear that they have seen as much as a 33 per cent decline in cereal output and 20 per cent decline in overall food per head in less than a decade. This is a faster rate of decline than colonial India saw in the inter-war period. All six countries liberalised. and engaged in a strong export drive during this period: four out of the six had 'intensive adjustment programmes' involving taking three structural adjustment loans (SAL), one took two SALS, and one started adjustment before 1986. All saw rising non-food exportables output per head at the same time that food output per head declined.

The following are country-wise figures of growth of 'non-food crops' in four of these which had taken SALs and implemented agri-export promotion (palm-oil and sugarcane have been left out since the source puts them in 'food crops' and does not give the country-wise figures of these crops so that adjustment by adding on to the other non-food crops is not possible. We had earlier presented these data in Patnaik 1992). The

crops in these countries. The inverse relation between exportables growth and food crops growth is clear though not one-to-one in the sense that the sharpest rates of decline in foodcrops is not necessarily associated with the highest rates of rise of export crops.

-----

The decline in foodcrops output including tubers and plantains for all 46 countries taken together (Table 8) was 11.5 per cent over the decade of the 1980s. This has effectively undermined food security, given that the initial levels were low to begin with : only 138.5 kg gross per head in 1980 compared to around 190 kg in India and 285 kg in China. By 1987-89 this had declined to only 122 kg. As we have seen the absolute figures may be underestimated; even if we revise all annual figures upwards by as much as 20 per cent, we obtain an initial figure of 166 kg, still well below the current Indian level, and a terminal figure of 151 kg. It is hardly surprising that a decline by 1989 of such a substantial magnitude in sub-Saharan Africa combined with decline in per head real income, should have created pre-famine conditions for the poorer majority of the population, such that any shock such as more than one drought year, a severe drought or accelerated inflation could set off actual famine. In 1992-93 there was a crisis in Zambia, Mozambique and Western Transvaal which most academics attributed only to the severe drought. Newspaper reports in June-July 1992 (especially *The Guardian*) however also wrote, significantly, of the substitution of locally consumed millets by horticultural exports having become very marked in the preceding years in these areas. Actual famine was only averted by a massive food aid effort, adding to the region's indebtedness. International financing and aid agencies have redefined 'food security' to mean, not self-sufficiency in food production, but making food available from donor countries in time to target populations to avert the more distressing manifestations of famine, which leaves untouched the basic structural cause of crises, namely the diversion of scarce resources to exportables.

The truth of the matter is that Africans with their low (340 dollars per head) and declining real incomes cannot compete in the global market against the superior purchasing power of northern consumers (15,000 to 18,000 dollars per head), any more than can the ordinary population of other low-income developing countries like India, Sri Lanka and Bangladesh (320-380 dollars), once their economies are opened up fully to the pull of international demand. They see their own land and resources being bid away by the pull of northern effective demand, from the production of the basic foods they need themselves to the production of exportables.

the land-use and cropping pattern of a tropical country will be substantially altered by the action of the powerful magnet of international demand with its own specific commodity structure, just as it was during the colonial period. Every time a northern consumer reaches out to the supermarket shelves for a bottle of vegetable oil, a tin of pineapple, a bunch of bananas or a packet of frozen strawberries, she is helping to bid away scarce tropical land from production of lowvalue food for locals to these exportables. These acts of 'free consumer choice' multiplied daily millions of times, translate back in to the activities of the transnationals which are busy promoting exportables production and agri-processing by contracting with local producers, displacing land and resources from foodgrains. The proposition that a reduction in food-crop production in a 'liberalised' economy leads simultaneously to a reduction in food availability is so contrary to the tenets of orthodox economic theory that an elaboration of it is in order even at the risk of some repetition. We may be asked for example: why cannot the exchange earnings from cash crop export be used to import foodgrains so that food availability is augmented rather than reduced through trade? The reason is that the very process of making exports available for the metropolitan market is one of demand deflation for food-crops, so that the supply as well as the demand for food shrink simultaneously. The foreign exchange earned from the export of cash crops is used partly for profit repatriation by the TNCs engaged in agri-business and partly for financing larger manufactured goods imports from the metropolis. Over time however even this exchange availability declines owing to the simultaneous pursuit of export promotion by a multitude of third world countries, all subject to structural adjustment; but this does not alter the fact of domestic demand deflation for foodgrains; if anything this deflation is tightened as the pressure to export increases with declining terms of trade. (Even if, taking a hypothetical case, agri-export prices declined to a point relative to the dollar prices of internationally traded foodgrains where the domestic production of the latter became profitable, such production would, given the fact of deflation, be earmarked for exports rather than domestic consumption. The link between production and availability of foodgrains in this case would have been broken but the latter would not have increased.)

·· ······ activities itections actention in them

In the case of African and other countries there has been an absolute decline of between 40 to 60 per cent in unit dollar price of primary products including minerals, over the decade (depending on the composition of the exports of the country concerned) and

no min in importantes prices. Terms or trauc internationally have shifted against primary exports oriented African countries by an average of 50 per cent over the decade and the adverse movement is continuing into the 1990s. With over 80 countries competing with each other under substantially identical Fund-Bank orchestrated programmes of agriexport promotion (given continuing recessionary conditions over much of the advanced world) it is hardly surprising that world prices of primary products and minerals have declined so much, to the great benefit of the developed world. Once the economy is locked into the regime of debt-conditional export promotion, the deflation of domestic demand for foodgrains becomes an endemic feature.

TABLE 7: INDEX OF FOOD OUTPUT IN SUB-SAHARAN AFRICA 1980-89

| Country/Group        | 1980   | Three Year<br>Average<br>1987-89 |

Source: African Development Indicators 1992 (UNDP, World Bank, Washington, DC) We have reworked the basic cropwise (up to six crops each country) and country wise (46 countries) data for ten years. 1980 to 1989, to obtain new aggregates of food crops defined as follows. Cereals include wheat, maize, barley, millets. Tubers include potatoes, cassava and yams, Plantains include bananas and plantains. The Sahelian countries had no recorded tubers or plantains output and produced about one-tenth of the total food output of the entire sub Saharan region Cereals, tubers and plantains have been aggregated following the convention 5 kg tubers or plantains = 1 kg cereals.

TABLE 8: ANNUAL GROWTH RATES OF FOOD AND NON-FOOD CROPS, SLILCTED SAP-IMPLEMENTING COUNTRIES IN SSA

| Country  | Period  | Non-Food | Food* |
|----------|---------|----------|-------|
| Ethiopia | 1986    | 37       | 9.0   |
| Kenya    | 1975-80 | 6.5      | -9.5  |
| Sudan    | 1980-85 | 13.9     | -2.3  |
| Nigeria  | 1986-89 | 11.3     | -6.1  |

Source: As Table 5. Food\* refers to the cereal crops; non-food excludes palm oil and sugarcane. The date for Ethiopia is openended in the data source.

A typical exporting country has had to louble volume exports, that is have export olume growing at a compound annual rate if 8 per cent over the decade merely in order o have the same stagnant exchange earnings it the end of 10 years, given the average fall by half in unit prices. Indians will readily ecognise the similarity with the dismal ontours of their own inter-war experience, when Indian peasants similarly faced with alling international prices were desperately jushing out more and more volume exports o maintain exchange earnings and finance he large obligatory transfer abroad. Replace transfer' with 'servicing of debt' and the ame scenario holds today. With over a secade of falling per head incomes despite indeed because of -liberalisation, the SSA ountries are castigated in the latest World 3ank Reports for failing to maintain volume exports at a high enough rate to compensate or adverse terms of trade!

EMERGING INVERSE RELATION BETWEEN AGRI-EXPORTS AND FOOD AVAILABILITY IN INDIA

Until recently large Asian countries like India and China strictly controlled their trade in agricultural products and insulated their peasant producers from the harsh impact of adverse movement in international terms of trade. There was relative stability of internal te,ms of trade and farmers enjoyed improvement over most of the period, compared to periods of adverse movement and large fluctuations in the international terms of trade, as Karshenas argues for the 1960s (Graphs 1a and 1b) While India and China may not have benefited from the apswing in commodity prices in the 1970s, equally they have not been subjected to the prolonged fall in primary product prices in the decade of the 1980s, which continues into the 1990s. In India this is now changing is the agri-export thrust gets under way. In fact by virtue of being a large producer the very fact of India's entry into the world market in a number of key commodities like rice and cotton is likely to depress international price

Starting from the 1950s both India and China had followed policies of promoting toodgrains production and building food security, China with greater success than India after the mid-1960s owing to its more egalitarian economic structure. In output Herais the Indian achievement was creditable sua e food output nearly quadrupled between 19 11 and 1991, from 46 mt for a population of 363 m to 170 mt for a population of b : m. The distorted pre-independence trend of a 10 times higher growth rate for exportable creps compared to near-stagnation for foodgrains, was altered dramatically to a phore normal equality of the two rates of In with: food output grew 30 ames faster at around 5 per cent while the non-tood crops growth also trebled to a similar rate. The earlier fall in per head production was reversed and a modest 16 to 18 per cent rise secured, which still has not compensated for the 25 per cent fall under colonialism. Moreover the composition of the average diet for ordinary people has worsened with a halving of the availability of pulses, hitherto the main source of protein for the poor.

During the five years since trade liberalisation in agriculture, foodgrains growth has slowed down, the average of annual growth rates being only 1.71 per cent. Within foodgrains while wheat and rice have an average percentage growth of 3.48 and 2.53 the pulses growth rate has averaged only 1.1 per cent while the coarse grains show the most alarming picture with lowest average growth rate of a mere 0.37 per cent. The gross area under foodgrams has declined by about 4 m ha over the reform period (Table 9): coarse grams have declined markedly by about 3 m ha and combined with decline in the pulses area accounts for the 4 m ha decline, which is quite substantial As we have been led to expect from the experience of all the liberalising countries discussed so far, the output of potential or actual exportables has grown much faster than the foodgrams in general within which the sub-category of coarse grains in particular is stagnant. Indeed the 1995-96 output is expected to finally be around 30 mionielower than the 1990-91 output of 32 mtorine The oilseeds like sunflower, sattlower mustard and soya are replacing the coarse groups in the low and ciratic rainfall areas of Andl va-Pradesh, Maharashtra, Madhya Pradesh, Gujarat and Rajasthan where the coarse or ons are traditionally grown as food scaples.

With such a decline in the production of coarse grains as a result of displacement by the exportables catering to domestic and foreign metropolitan demand, what is happening to the consumption of the labourers and small farmers in these areas for whom these coarse grains like bajra, jowar and ragitare the traditional food staples? This is a question that researchers should examine carefully. Not the most ordent

theraisers can argue, given the fall in real wages of rural labour and rise in poverty, that these classes are switching over to superior cereals. In fact the demand compression through real income decline of labourers and small farmers is the economic mechanism through which diversion of resources is made possible from the local food staples to the exportables. Their level of consumption must of necessity have declined.

#### SUPPORT FOR AND OPPOSITION TO NEW POLICIES

What are the main forms of growing agriexports; who will gain, and who will lose, from the new export-orientation of Indian agriculture? These are the questions we address briefly here. Foreign companies entering into agreements for agro-related business in India numbered 293 during 1986 93 compared to 111 during the 35 preceding years. A number of domestic large companies like Tata and Modi have also shown an interest in this area. The commodifies which are expanding today and are tikely to grow in future to meet metropolitan demand are rice, cotton, vegetable oils, animal feeds, vegetables, flowers, ornamental plants and orchids, prawn and other sea food, and hardwood timbers for luxury furniture and house fittings. All of them involve problems by way of displacing food growing land, displacing hired labour, and some by causing Ereversible forest and land degradation. A minority of capitalist farmers enter into these areas for short-term profitability and act as the conduits through which exportables are pumped out to meet metropolican demand

At the current exchange rates are is compensive on the international market and the expect of the its prowing fact from a low of an base. The main area of commercial tree production is North India which has been supplying so for ever two thirds of the rice production system (the areas where rice is a traditional staple crop for the growers are in eastern and southern India but only one-third of output is sold compared to overninetenths in northern India. With exporting albering momentum the government has to

compete with the global market to keep its own ration shops supplied. The result has been a sharp rise in the administered prices of foodgrains. In the new atmosphere of licence to profiteering, a larger fraction of stocks meant for the ration shops appear to be getting diverted to the free market. Ration rice when available at all, costs now double what it did five years ago, making the gap between the open-market and ration-shop price so small that many lakhs of the poor have been priced out, and offtake from the ration shops is exceptionally low.

It has been argued cogently that since India is a large producer accounting for 22 per cent of world rice output whereas world trade in rice is around 4.4 per cent only of world output, India's entry on any scale into the world market, is likely to depress the price (Nayyar and Sen 1994). Thus by exporting a mere 5 per cent of its own output India would augment world market supplies by 25 per cent exerting a downward pressure on the price. We are very likely to be caught in the current African scenario of larger volume exports at falling prices. Groundnut (35 per cent of world output), cotton, wheat, sugarcane (all around 8 to 10 per cent) are other crops where India has a substantial weight in world output.

Raw cotton demonstrates the problem to domestic consumers posed by indiscriminate and unregulated agri-exports. Even before full scale liberalisation, there was a ten-fold rise in exports in 1990-91 compared to 1989-90. While volume exports have fluctuated since 1991, it has averaged 148 thousand tonne annually during 1991-92 to 1995-96 or over four times the average level of 35 thousand tonne before 1990-91. The price of raw cotton has trebled and yarn price has doubled over the same period. Lakhs of handloom weavers whether independent or in co-operatives are facing sharp income decline while small powerloom enterprises are also reportedly closing down. In Andhra Pradesh in 1990 many weavers had committed suicide as they were ruined by the sudden rise in yarn price. With the present sharp inflation economic distress faces weavers again, to the extent that the government has been forced by their acute distress to announce a temporary hank yarn subsidy scheme, despite subsidies being anathema in the Fund-Bank theology.

Large industrial houses have been acquiring agricultural land in the traditionally paddy growing coastal areas of Orissa, Andhra Pradesh and Tamil Nadu for conversion to prawn fisheries while rich farmers have also joined in since at present the returns are high. The rapid growth of prawn fisheries in coastal and paddy-producing land during the last five years, is generating enormous tensions between the companies and individuals engaged in this

and environmentalists, fishermen and the local labourers displaced from paddy production, on the other. Illegal and semilegal land-grabbing by the exporters, prawn raising leading to salination of soils making them unfit in the long run for paddy, depletion and salination of groundwater resources by the prawn fisheries affecting neighbouring farmers, diseases caused by effluents, loss of traditional access by local fishermen to the coast and beaches with privatisation, are some of the many issues involved. The immediate loss of livelihood for agricultural labourers with the labour-intensive paddy being replaced by the fisheries, has provoked resistance by labourers in Tamilnadu, organised by the octogenarian Gandhian leader, S.Jagannathan. However given the vertiginous rise of carnings at present from sea-food exports of which prawns comprise over three-quarters, and with the government strongly backing it, the expansion is likely to continue. As with every exported commodity such as cashewnuts earlier, prawns which today are highly prized by the Northerner as a protein source, have also been priced out of the reach of the Indian domestic middle class whereas it routinely figured in its consumption basket a few years ago. However as long as exports affected the consumption basket of the middle class alone the argument against it was still weak. This is no longer the case; the export drive has started affecting the basic availability of staple foodgrains for the poor.

Other avenues of ongoing displacement of foodgrains meant for human consumption, include vegetables and fruit production under contract to the TNCs which started with Pepsico International's activities in Punjab; the dissemination of genetically engineered sorghum seeds by Cargill in an apparent attempt to initiate a replication of the Mexican story in Karnataka (which has been stemmed by opposition from the militant farmer's movement, expansion and export of cut flowers; and the rapid growth of sunflower and soya production in hitherto millets producing land in northern and peninsular India. (The sunflower is processed to give 'healthy' oil for export, the soya is exported as livestock feed concentrate). There has also been a mushroom growth of companies promising (via press advertisements) upto 70 per cent rate of return on investment in teak plantations and horticulture for export The land for these ventures have been acquired very often by dubious means and by encroaching on common property resources. With proposals to amend the existing law regarding 'ceilings' on landholding, some state governments are sending clear signals that implementation of the existing land reform laws are to be shelved and indeed reverse land reform caried out

lucrative export business on the one hand, • in tayour of the untettered growth of exportand environmentalists, fishermen and the oriented agro-capitalism.

It is reasonably clear that the new trends will lead to an accentuation of the economic differentiation which already exists strongly in rural society, to a point of sharp dualism between a minority of export-oriented capitalist farmers and companies out for quick profits regardless of social costs on the one hand, and a mass of cultivators whose returns from the domestically consumable crops falls as a direct result of the relative price shifts inherent in the new policies and their active promotion by government. The livelihood of rural labourers is under threat and irreversible environmental problems are in the making.

There have been two diametrically opposite sets of responses from the farmers' movements in India: a minority response. strongly backing the new policies, and clearly representing the interests of the capitalists and business houses anticipating quick profits. It would be fair to say however that the majority of farmers are alarmed by the implications of the new policies by way of the displacement of foodgrains, loss of employment, environmental damage and extension of control by big industrial houses and TNCs. The movements led by Nanjundaswamy in Karnataka, by Jagannathan in Tamil Nadu, by Banka Behari Das and others in Orissa, by Sunderlal Bahuguna in UP are all in their different ways, against

The new policies. The struggle of the labourers in Tamilnadu is supported by the Communist parties as well. These protests are buttressed by the protest against environmentally damaging industry such as the proposed Du Pont-Thapar acrylic plant in Goa, which has led to police firing and deaths.

Some very limited successes have been scored for example in the widespread public campaign against the provisions of the Dunkel Draft during 1993-94, which put pressure on the Indian government to ensure the continuation of the public food distribution system (though it is being contracted) and to clarify that farmers' rights to grow and exchange their seeds will not be affected. The amendment to the Patent Act 1970 in accordance with GATT '94 requirements, has been blocked so far by widespread opposition in Indian parliament. Direct action by farmers and local environmental activists has prevented the plans of Cargill to set up sorghum seed dissemination in Karnataka and a giant saltproduction project in Gujarat.

Decline in area sown to foodgrains and other crops in a particular year is not uncommon if rains fail; but recovery is usually fast. For the first time in Independent India, we find a persistent decline in the absolute area under foodgrains; the figures for all the years after 1990-91 are distinctly lower than that for any year between 1980-81 and 1990-91 (Table 11). It is hardly surprising that per capita food availability, looking at comparable years has declined (Table 10). This is on the conventional official definition of availability, without taking account of any possible increased diversion of grain to sustain fast growing livestock production. The actual situation may of course be much

### **Agricultural Development**

### **Imperatives of Institutional Reform**

### A Vaidyanathan

This paper underscores the crucial importance of institutional reform, particularly in the domain of public systems, for sustained technical progress and output growth in agriculture. The scope for privatisation is limited in irrigation, research and extension and other infrastructure facilities. All of these will continue to be mainly the responsibility of the public sector. Unless the public sector's efficiency in mobilising resources and managing these facilities is vastly improved, trade and price policy reform will not make a significant difference to the pace of agricultural growth.

THE current debate on 'state vs markets' centres on the desirability of the state getting directly involved in production and distribution, as well as on the extent to which it should seck to control the activities of individual enterprises. It is widely acknowledged that the record of government and its agencies in implementing their programmes, using resources efficiently, maintaining satisfactory standards of service and showing resilience and the capacity to innovate, has been less than satisfactory. Attempts to regulate private sector activities in pursuit of equity and other social objectives has proved to be not only cumbersome, but their effectiveness is also in doubt. Part of the problem is that those who are sought to be regulated often succeed in capturing the regulatory authority. Attempts to control the behaviour of enterprises has also reduced the incentives for efficiency and innovation, and restricted the freedom and flexibility to pursue these goals. There is therefore a growing clamour for the state to drastically reduce its involvement in production/ distribution and give up discretionary controls operated by the bureaucracy. Enlarging the scope for private initiative and leaving it free to function in a competitive market environment will, it is argued, result in greater efficiency, faster growth and speedies elimination of poverty.

The 'state vs market' debate in India which started with the state's role in relation to industry has spilled over into agriculture. There is an articulate lobby advocating total free trade in agricultural products along with a phase-out of input subsidies and regulations which interfere with the free market. As in industry, these measures are expected to result in more efficient use of resource and faster growth. This essay questions the above on the following grounds: (a) the government's 'control' over agriculture is far less in scope and detail compared to industry; (b) removal of controls per se will not bring about faster technological change and larger investments essential to accelerate agricultural growth; and (c) 'privatisation' is neither the only nor the best solution to the deficiencies of the public sector. Many activities needed to sustain agricultural growth must necessarily be in the public domain, so that the restructuring of public agencies, broadly defined, to ensure that the support facilities are made available in adequate measure and efficiently is as important as making the markets work.

### Institutional Features of Indian Agriculture

Agriculture in India is perhaps the least affected by government participation or regulation. Of the various resources used in agricultural production, arable land is almost entirely owned and cultivated by millions of peasant households. The bulk of them have very small holdings (56 per cent of the holdings are less than 1 ha). Owner cultivation is preponderant. Reported tenant cultivation - which is likely to be an underestimate-currently accounts for barely 15 per cent of the area, A sizeable, but declining, amount of land in rural areas is classified as 'common land' whose use and access is regulated by village communities on the basis of traditional custom and usage. Much of the wastelands and forests are state owned. But communities living near forests are permitted restricted rights of access to and use of forest produce.

There is hardly any direct government intervention in the production and investment decisions of the farmers. But the government does influence the legal, material and economic environment in which farmers operate Regulations concerning weights and measures, produce grading, seed certification and produce markets seek to ensure that farmers are not exploited by traders' unfair trading practices. Ownership and cultivation of land is subject to laws and regulations concerning ceilings on landholding, tenancy arrangement and development and use of water resources. The right to property is protected by the Constitution but it is not an unrestricted right. The state can, and has, enacted laws modifying or even abrogating existing rights in order to serve social objectives. Land reform legislation (including those relating to tenancy and

ceiling on land holdings) is meant to ensure a more equitable distribution of land, the basic productive resource of agriculture. Laws for consolidation of holdings and regulations concerning exploitation of forests are meant to facilitate more efficient use of land

Government directly owns a substantial part of waste and forest land and is, in principle, the ultimate 'owner' of water resources. The construction and management of large surface irrigation is entirely in the hands of government. Substantial development of small surface irrigation works took place in the distant past mostly through local effort and currently account for approximately one-eighth of the total irrigated area. The government has increasingly assumed responsibility for maintenance of main structures and for major repairs/renovation of small surface works. It does not, however, interfere or regulate their internal management. They are maintained and run by the user communities based on local usage and customs. Wells, tubewells and pumps for lifting groundwater are mostly in the hands of individual farmers. But they are subject to government regulations meant to serve the interests of equity and sustainability.

The state plays a major role in providing other infrastructure, notably research and extension, road networks, marketing yards and rural electrification. Electricity generation and distribution are mostly in the hands of government and its agencies. Public enterprises play a substantial role in production of improved seeds and fertilisers. A significant proportion of these inputs and credit is also distributed to farmers through co-operatives and other public financial institutions. The private sector is the principal source of agro-chemicals and all forms of agricultural and irrigation equipment. Processing and trade are mostly in the private sector and agricultural markets are largely

The state has actively promoted the cooperative form of organisation in the sphere of agricultural credit, marketing and processing. Besides defining the legal framework in which the co-operatives are to function, the government has provided them substantial resources by way of loans at subsidised rates, underwriting losses and occasionally writing off principal and interest due on outstanding loans.

Finally, government policies relating to support prices, procurement of agricultural products, taxes and subsidies and foreign trade affect the allocation of resources via the prices of agricultural output relative to inputs, the relative prices of different crops, and prices of farm products relative to those of manufactures. Over the years, Indian government policy has resulted in substantial and growing subsidies on agricultural inputs. While most crops are guaranteed minimum support prices, restrictions on internal market and on foreign trade are claimed to have depressed product prices. Manufacturers have the benefit of high tariffs which are denied to agriculture. This means that agricultural products have received a much lower degree of effective protection compared to manufacturers.1

During the last five decades, agricultural output has grown by 2.5 per cent to 3 per cent per annum: more than double the overall rate recorded in the first half of the country. Since the scope for extending cultivated land has steadily diminished, the sustained growth in overall output reflects a progressive acceleration in the rate of yield improvement. There is little doubt that massive government investments in irrigation, research, extension, and other infrastructure, together with the expansion of institutional credit and the policy of guaranteed support prices and subsidised inputs have contributed significantly to this process. However government's role in agriculture has attracted

One major strand of criticism is that policies have discriminated against agriculture by depressing domestic agricultural prices relative to prices prevailing in the world market and relative to manufactures. This, it is alleged, has acted as a strong deterrent to private investment in agriculture, spread of improved technology and hence yield improvement; tilted income distribution to the disadvantage of rural areas; and encouraged wasteful, and ecologically undesirable, ways of using inputs like water and fertilisers.

The other major criticism relates to the unsatisfactory performance of public sector programmes for land and water development, research, extension and other agricultural infrastructure Unsatisfactory performance in these activities is manifest in the nonfulfilment of targets for irrigation and fertilisers; inflated costs; poor quality of service; uneven progress of research as between crops and between irrigated and rainfed agriculture; the persistence of large gaps between actual yields and potentials demonstrated by researchers. Regulations, intrastructure and supply of inputs. Hence on production and distribution of fertilisers. seeds and other current inputs by private sector and co-operatives has contributed to inefficiency and high costs.

In this context the advocates of liberalisation attach great importance to (a) removing all restrictions on imports and exports of agricultural products; (b) phasing out subsidies on agricultural inputs; (c) opening the input production and distribution to the private sector along with removal of all controls on their production, distribution and pricing; (d) enlarging private sector participation in surface irrigation, research and extension; and (e) the removal of land ceiling legislation and restrictions on the land lease market, and allowing private corporations (domestic and foreign) to acquire land for raising crops and forests. That non-price factors (irrigation, technology and cultivation skills) have a role and need improvement is conceded, but changes in the incentive environment are seen to be more important and urgent. There are of course strong differences on these issues.

There is little disagreement about the need for eliminating input subsidies. They are inequitable, inefficient and a heavy drain on budgetary resources. Free trade seems likely to raise the average domestic price of agricultural products by a substantial extent. Relative prices would change significantly. Reduction in the tariffa - currently in process should contribute to improving agriculture's terms of trade if it results in lower prices of manufactures. These effects will however be partly offset by the elimination of subsidies.

Whether such a package, which will benefit some classes of farmers and some regions at the expense of others, will be politically feasible is one question. The more fundamental issue is whether, even if these reforms result in a sizeable net improvement in the overall terms of trade, they would by themselves induce a strong aggregate supply response leading to a sustained faster rate of output growth.

Available evidence is patchy and consists of a very limited number of studies for the country as a whole. They show that the aggregate supply response to price changes is quite low; that they can account, if at all, for a small fraction of the observed growth; and that the growth of production is largely determined by non-price factors, specifically the availability of land, water, fertilisers and other key inputs, the stock of proven techniques (embodied in the seed varieties, agro-chemicals agronomic practices, energy sources) and the rate at which they grow.2 How effectively these techniques and inputs are used is conditioned in an essential way by the agrarian structure and the efficacy of organisations responsible for the basic

the importance of focusing on institutions involved in, and influencing, agricultural production.

#### AGRARIAN ORGANISATION

Discussions on institutions used to centre on agronomic structure modes of production and the role of land reforms in promoting agricultural growth. Over the years, attention has shifted to the role of different types of state intervention to help poor segments of rural society to raise the productivity of their resources and augment their resource base. The current debate on liberalisation in its preoccupation with the question of state vs markets appears to have relegated land reforms and agrarian organisation into the background. Indeed questions are being raised about the desirability of persisting with the kind of land reform programme which has been pursued so far.

There is a school which argues that restricting the extent of land which individuals and households can own and redistributing the surplus to achieve a more egalitarian distribution of land-which has been the central thrust of land reforms so far-are not only unsuccessful but also impede efficient use of technology. Abolition of land ceilings, allowing greater scope and freedom for tenancy arrangements mediated by the market and permitting private corporate enterprise to develop large-scale farms would, according to this view, promote more effective use of technology and contribute to faster growth.4

There is little evidence of any significant scale economies in agriculture. There is far more compelling basis to believe that smaller farms have an incentive to use labour more intensively and that this leads to higher production per unit of land. Experience shows that small farms have, in due course, adopted new varieties and inputs as widely and as intensively as large farms. Any move which will dispossess small holders of their mair source of the subsistence is not feasible and certainly not politically acceptable.

The disadvantages of small units in respecof access to inputs can be substantially overcome by public intervention to ensure them better access to credit both in terms of quantity and cost. The solution to fragmentation of holdings is consolidation of holdings. Both these have been part o government policy. That the interventions have been less effective than expected especially in the case of consolidation, is essentially an institutional failure.

Some of the disadvantages of small fragmented holdings can in principle be overcome by co-operative organisation. It theory, co-operative farming, where members' land is pooled and cultivated as

a single unit, could make octici use of failu and also reduce costs by improved bargaining strength in both input and output markets. Co-operatives in processing and marketing potentially offer similar advantages. In the case of credit, a co-operative whose membership consists of both depositors and borrowers (who know each other, are linked in social ties and are familiar with each other's activities) will be able to better monitor use of credit, reduce risks of default and therefore can borrow at a lower cost. This, along with the moral appeal of cooperation as a form of mutual help meant to promote the collective interest of the group rather than maximise profit, has been the rationale for the government policy of actively promoting co-operatives.5

In point of fact, co-operatives have made no headway in cultivation. Co-operatives have come to be a noticeable presence in processing and marketing. It is in the sphere of rural credit that they have become widespread and significant. But they in general do not meet the criteria of democracy, mutual help and self-reliance. Excessive dependence on borrowed funds and government subsidies, high costs, high incidence of overdues and defaults are all indicative of their poor state of health. Nor has the policy of channelling rural credit increasingly through the commercial banking system been conspicuously more successful.<sup>6</sup>

#### ROLE OF PRIVATISATION

There are also several problems with the way infrastructure support and production and distribution of inputs for agriculture are organised and managed. The poor performance in all these activities has attracted well deserved criticism. In this context, privatisation of production and distribution of inputs is being advocated by those who see the free market mechanism as the best guarantor of efficiency.

It is however necessary to distinguish the question of ownership from the need to eliminate in some cases, and drastically reduce and simplify in others, governmental intervention in investment, production and marketing decisions of individual enterprises. Where a commodity or service can be defined unambiguously, every user or buyer can access and use them independently of others, and the quantity bought or used by individual buyers/users can be measured accurately at a reasonable cost, there is no need for detailed government direct controls on individual enterprises be they private, co-operative or government. This is the case with fertilisers, agro-chemicals seed and farm equipment. In all these activities, a process of reducing government intervention is under way. But clearly much more needs to be done for example in the case of fertilisers. Whether existing public sector enterprises in these activities should be privatised and their role in further expansion should be restricted, depends crucially on whether public enterprises will be made fully autonomous and left to fend for themselves without any budgetary support.

Privatisation is, however, not the solution in the case of public goods (like research and extension) and of improvements to common pool resources (of which water and watersheds are the most important examples). The prospect of private sector involvement in research is limited: private companies are mostly interested in investing in research on hybrids and bio-engineered speciality crops from which they expect high returns. Producers of fertilisers, plant protection chemicals and farm equipment also invest in developing and propagating new or improved varieties of these inputs. But their efforts tend to be focused on promoting the sale of their particular products. The task of varietal improvement for open pollinated staple crops, evolving cropping systems and management practices appropriate under different agro-climatic and soil moisture conditions, promoting more efficient and eco-friendly use of chemical inputs, and developing more cost effective techniques for soil and moisture management (especially on rainfed lands) have not and are unlikely to attract private enterprise. The improvements resulting from much of this research being in the nature of public goods are best handled by public agencies. It is not surprising that almost everywhere these activities are vested with public agencies.

The potential of technology developed and proven in the research stations for raising productivity and/or lowering costs is not fully exploited. It is argued that the government extension service is neither equipped nor has the incentive to transmit all this knowledge to the farmers and provide location-specific advice on appropriate crop varieties, input use and management practices. If this is true, there should be a significant role for non-government agencies to render these services to farmers on a commercial basis. But the fact is that private enterprise and non-government organisations have not entered the extension field while they have spread rapidly in providing tractors and other farm equipment services on hire. It is essential to understand the reasons for this before the role of privatisation in extension services can be discussed meaningfully. Many elements of infrastructure (especially elementary education, rural roads and electrification) are also in the nature of public goods or generate large externalities. Public provisioning to ensure all segments of the population access to these facilities is therefore socially desirable. Large surface irrigation systems involve huge investments which are beyond the capacity of beneficiaries to mobilise. Considerations of equity in access are important here also. Similar problems exist in defining rights and obligations of different groups in areas covered by soil conservation or watershed projects. Groundwater lends itself more readily to private exploitation largely because the scale of the facilities can be adjusted (over a wide range) to the needs of individual users and their capacity to mobilise the needed resources.

However, where - and this is invariably the case - a number of farmers draw from the same aquifer or reservoir, there is need for some mechanism to make sure that exploitation is equitable and sustainable. In all irrigation works as well as soil conservation and watershed improvement schemes, uses and users are linked in a complex interconnected network not only within the command of a particular scheme but as between different schemes falling within the same river basin. Under these circumstances it is essential to lay down the principles on which the claims of different users in a given system and between different systems falling within a drainage basin are to be decided; the basis for sharing costs and benefits among the concerned groups; and the institutional framework in which these principles are to be implemented. This can be done only by the government.7

### IMPROVING THE REGULATION FRAMEWORK OF RULES AND REGULATIONS

On a broader plane, government per se defines the legal framework in which individuals and organisations (public and private) function; and sets up mechanisms for ensuring that the rules are complied with by all concerned (including government) and that conflicts are resolved in a fair manner. No other entity can perform this function. Deficiencies in both the design of the legal framework and the way it works affects the performance of the economy as a whole and its various components, including agriculture. The plethora of existing laws and regulations are complicated, cumbersome and, not infrequently, detective. Some laws are administered in ways quite contrary to their intent and spirit and enforcement is genarally weak, if not ineffective.

Take, for example, the case of water. Being a common pool resource, it is important to have clearly defined rules for determining the rights of ownership and use of different claimants to a common source (be it a particular reservoir, aquifer or a river basin). The state is recognised as the ultimate owner of water resources with the right to regulate its development and use. In the case of surface water, no impounding or diversion

approval. The development of groundwater is also subject to government regulation. Being a common pool resource, clearly specified rules are needed for determining the rights of access and use to different areas, different uses and different users.

There are laws (Inter-State River Disputes Act and the River Based Act) which provide for institutional mechanisms to settle issues concerning relative entitlements of different riparian states in a river basin and to ensure optimal use of the basic resources. But the principles by which the entitlements are to be decided have not been codified. The task of deciding which of the several principles (such as prior use, quantum of water originating in a state, 'just and optimal use') should be used, in what combination and how have been left to be decided by tribunals.

The central legislation however applies only to allocation between states. The determination of relative rights within a particular state have been left to be decided by their respective governments. None of them have enunciated any clear principles for deciding this matter. Disputes are taken to courts which have generally upheld the rights of prior use, but this principle is not always respected, sometimes even in the face of explicit court judgments.\*

In the case of specific surface projects, users' entitlements in small, and usually old, works serving individual communities are defined by tradition and usage rather than by formal legislation. Significantly, however, though the conditions of agriculture and, in many cases, even the character of traditional local systems have changed, the traditional allocation rules apparently remain the accepted points of reference in the communities. The government does not enter the picture.

Even in the case of systems constructed and managed by the government, the legal status of the entitlements of even registered ayacutdars is not clear. Nor is there a well specified contract spelling out the rights and obligations of the system and the irrigators. Wide divergences between declared entitlements and actual allocations are commonplace. And there are no codified principles for tackling this situation. This disjunction gets adjusted in practice more or less in an ad hoc manner reflecting ground realities of geography and power.

Similar problems exist in the case of groundwater. There are government regulations to check over-exploitation. A landowner, by law, has the easement right to tap whatever resources exist under his land. Neighbours are also entitled to be protected against adverse consequences of an individual's exercise of this right. But the procedural and resource costs (or transaction costs in current parlance) of securing this

is unlimited open access to this common resource. The problems of defining what sustainable use is, the basis on which it will be determined in specific areas and the specification of individual rights remain largely unaddressed.<sup>10</sup>

Lacunae are also apparent in land laws. For instance, the basis for determination of land ceilings varies widely. Some define it with reference to individuals, others in relation to households; some take into account variations in household size and variations in land quality, others do not; some allow exemptions for specified uses, others do not. The problem is not so much the lack of uniformity as the lack of a rational link between the specification of the ceiling and the objectives meant to be accomplished by it. The preconditions for making the law effective-in terms of the availability of accurate information regarding existing land rights, its accessibility to all affected parties, and creating speedy and affordable procedures for settling claims and disputes - are often missed out even in the design of the legislation and invariably in implementation.

Innovative schemes-like integrated watershed management, community participation in afforestation and forest management, and promoting user involvement in management of irrigation works-have been impeded by inadequacies in legal provisions. There are of course inherent difficulties in organising collective action in a society marked by economic inequalities and social differentiation. But these are compounded by the lack of the legal framework to facilitate their functioning. Thus if integrated watershed management is to be workable, there should be some explicit codification of the rights, as well as attendant obligations, of the affected communities and their constituents in respect of land which are 'owned' by the panchayat, the revenue department, the PWD and the forest department. Similar problems exist in the case of forests as well.11 This aspect has not so far been addressed seriously. In the case of irrigation, attention has for the most part concentrated on the forms and functions of the user organisation at the level of individual villages or outlets, without addressing issues regarding their place in, and their relationship to, the system management as a whole.<sup>12</sup>

Defects in the law are compounded by weak enforcement. In part this reflects difficulties of monitoring compliance. In the case of ensuring correct weights and measures, grading of produce and checking adulteration, the activities are so dispersed that monitoring by a centralised bureaucracy is both impractical and far too costly. Also, there is a high chance that functionaries responsible for enforcement – who are the

with the violators and fail to act on complaints. To some degree, functionaries responsible for enforcing the law are handicapped by the inadequacy of resources to monitor violation. Incentives for strict and fair implementation are weak. These problems are greatly compounded by wide-spread bureaucratic and political interference in the constitution and functioning of regulatory authorities either to please vested interests, or for fear of political agitation, law and order problems and attendant loss of electoral support.

Since violation of any regulation benefits some at the expense of others, one may ask why those adversely affected do not take recourse to legal remedies or exert direct pressure on the enforcement agencies to take appropriate corrective action. That this does not happen at all, or does not manifest itself strongly, is one of the puzzling features of the Indian scene. Inadequate knowledge of the relevant laws and procedures among the affected public, the high cost (in terms of time and resources) of seeking and securing redress are surely part of the explanation. In the absence of an informed public opinion, backed by strong non-governmental organisations in civil society, it is not possible to mobilise the resources and effort needed to ensure corrective action.

Finally, there is the problem of abuse of laws: co-operatives being an excellent case in point. The law on co-operatives, as it stands, gives the state bureaucracy far too much power to interfere in their working. The opportunity and the occasion for such intervention has grown partly because the societies did not have to mobilise their own resources and have come to depend mostly on soft loans from the government and public sector financial institutions. Under these conditions, societies have little incentive for prudent management of their resources. The tendency of governments to condone defaults and even write off large parts of accumulated arrears from members for purely political reasons has further weakened these institutions. Over a period of time they have come to be used as conduits for government subsidies and political patronage to a point where political interference in the affairs of societies has become rampant. In many states elections of societies' office-bearers by their respective general bodies, though mandated by the law, have been suspended and the government has taken to appointing the key functionaries on political considerations.

One of the major areas of institutional reform would be to drastically reduce government supervision and control over co-operatives and its power to suspend the democratic functioning of the societies. At the same time it is essential to reduce reliance of the co-operatives on state financial support

n the form of loans and subsidies (especially waivers of loans). Societies must be required o mobilise a sizeable part of their resources lirectly through deposits and to observe forms expected of prudent and well managed inancial institutions. The capacity of societies at all levels to access the financial narket should be contingent on their record of prudent management.

Attempts to correct the deficiencies in the egal framework thus involve far more than eview of gaps and defects in writing laws and regulations and rewriting them to make sure that the rights of various agents involved, he rules governing their mediation and nechanisms for conflict resolution are made :learer, more complete and coherent. This by itself is not enough because the problems are complex and vary across space and time. However, our knowledge of these problems and their solutions is inadequate. Therefore even as the formal laws must enunciate clear general principles, they must leave sufficient oom for flexible application of these in specific contexts and for adaptation in the ight of changing circumstances, new cnowledge and experience. Agencies charged with enforcement of rules and adjudication of disputes must be assured of adequate personnel and resources; and the freedom to make and enforce decisions on violations and disputes without any executive or political interference.

But one cannot rely wholly or even largely on government regulatory agencies. It is necessary to give much more attention to ways of internalising incentives for monitoring, enforcement and conflict resolution. Several possibilities are available: (1) provide space for parties affected by a particular project to negotiate a mutually acceptable contract of cost and benefit sharing consistent with clearly stated general principles; (2) make the public more aware of the regulations and ensure free and public access to relevant information on the working of concerned institutions; and (3) actively encourage non-governmental organisations to keep a watchful eye on violations and take them up with the competent authority.

### IMPROVING EFFICIENCY OF PUBLIC SYSTEMS

Improvement in the framework of rules and regulations and in the way they are administered, together with changes in the incentive environment resulting from dismantling of controls, will generate both pressures and opportunities for greater efficiency in the private sector. But by themselves they are unlikely to make a significant difference to the performance of government and its organisations. The volume of resources which the public sector can mobilise for land development, irrigation, research and other supporting infrastructure,

and the efficiency with which these facilities are managed has a direct bearing on the growth of agricultural production. Without considerable improvement of public sector performance in both respects the availability of these supporting facilities, their quality and cost could make even the sustenance of past growth rate, not to speak of accelerating it, difficult.

In addressing this problem, a clear distinction must be made between government per se and government agencies/undertakings engaged in production and distribution of goods and services. The redefinition of the relationship between the two is an essential first step to more efficient functioning of the latter. The other ingredients of reform should focus on redefining the manner in which decisions of public undertakings are made, implemented and evaluated, and on restructuring of their internal management to make it more conscious and capable about efficient functioning.

The concept of the public sector also needs to be broadened to include not just undertakings owned or controlled directly by government, but also of non-government organisations (including co-operatives, public trusts, charitable institutions and other constituents of civil society) which are informed by purposes other than private profit maximisation. The public space, in other words, is much wider in scope and more differentiated than government and undertakings under its direct control. Providing space and encouragement to the activities of such autonomous, nongovernmental organisations besides being desirable in itself, would contribute to improving the functioning of public sector institutions.

A general problem with all government and public sector undertakings is that technical and economic scrutiny of investment proposals is not as searching and strict as it should be. Even in the case of projects involving large investments the process is entirely internal to government. Watchdog institutions (such as the Comptroller and Auditor General) come into the picture only after – and usually long after – the project has been implemented. By which time it is too late to correct mistakes. Moreover these institutions do not have the resources or the expertise to conduct a proper techno-economic audit.

Information regarding the details of investment projects and their implementation in the public domain is usually far too limited; and access to this information is deliberately restricted. Often, the necessary expertise is not easy to assemble outside of government. Public agitations on projects like Narmada, Tehri, nuclear power and chemical factories have faced these handicaps. They have set in motion attempts on the part of NGOs to

tap non-official expertise to examine the projects and alternatives. But this needs to be done on a wider scale and in a better organised manner. Moreover measures to promote greater transparency and to provide opportunity for public scrutiny of decisions on major projects are essential to achieve public accountability.

The other general problem has to do with the criteria for assessment of the performance of government and public sector projects. Not all government activities can of course be judged by their ability to make profits, or even to cover costs. The provision of public goods and facilities with sizeable externalities belong to this category. But public sector activities engaged in production and distribution of marketable goods can be subjected to this test. Profit maximisation may not be the purpose of public investment, but this does not mean that they should be absolved of the responsibility to produce the output expected of them at as low a cost as possible; and that, except where the government as a matter of explicit policy decides otherwise, they earn sufficient revenues to cover their operating and capital costs.

That public sector undertakings are required to serve strategic and social objectives (employment, balanced regional development, protection of vulnerable groups, etc) is often used to argue that financial profits or losses are no basis to judge their performance. This is a specious argument. For the costs which public undertakings have to bear on account of these functions can be quantified, even if only approximately, provided their social obligations are explicitly stated. The problem arises because governments find it politically convenient to obfuscate the issue by not specifying these obligations and by keeping the boundaries of the undertakings' finances and government budgets deliberately fuzzy.

This makes it difficult to judge how much of the losses (or low profits) of public undertakings is attributable to inefficiency in conducting their principal business and how much to the cost of fulfilling social obligations thrust on them. And so long as governments are willing to use their budgetary resources to underwrite the losses of public undertakings, the latter have no incentive to raise the issue on their own. At that same time since there is no threat of bankruptcy or closure, the pressure on their managements to improve efficiency is greatly weakened. This undesirable situation has also become untenable because of the deteriorating finances of both governments and their undertakings. Reforms are imperative.13

All public undertakings engaged in production or trade must be sharply differentiated and separated from government proper. This has already happened to a large extent and

limited companies, statutory corporations and boards. However there are a few activities which are still managed by departments of the government. In relation to agriculture, surface irrigation is perhaps the most important activity in this category and one which should be vested with separate organisation(s) outside the government.

Far more important than organisational separation is managerial autonomy. Apart from the overall policy framework of the government relating to the economy and particular sectors, and stipulations regarding the minimum return on investment, the government and the legislatures should not interfere with decisions relating to investment, personnel, contracts, production and pricing policies of individual undertakings. These decisions, as well as matters regarding internal organisation and staff deployment, should be left entirely to the management. The government should also accept and adhere strictly to the principle that it will not bear any part of the losses of such undertakings and that they will have to mobilise their additional capital needs directly from the market. If the government decides, on larger considerations, that any of the undertakings should provide concessions to particular regions or classes of users, these stipulations should be made explicit, the cost involved (in terms of extra costs or revenue foregone) quantified in the accounts of the enterprise and reimbursed from general revenues.

Where the economies of scale and scope are large and the potential for monopoly is high, the government will have to put in place a regulatory system to ensure that monopoly power is not used in fixing or revising prices. It is the function of the regulatory authority to lay down (and periodically revise) norms regarding capital costs, capacity use and rate of return to capital; and to decide on proposals from individual utility undertakings for fixing or changing rates. Such authorities are conspicuously absent in India. All the decisions are taken by the government. The creation of regulatory authority independent of government is essential even if the utilities are to be wholly in the public sector; and more so if private enterprises (whether independently or in joint venture with the public sector) are permitted to play a larger role.

These reforms would generate external pressures for improving efficiency and enable the organisations to take appropriate steps to this end. But they need to be reinforced by reforms in their internal organisation. In some cases, (e.g., small, local irrigation works, elementary schools and rural roads) considerable gains in efficiency of operation and use of available facilities as well as collection of charges would accrue if their

entrusted to user communities or cooperatives subject only to maintenance of certain general standards. But this is not always possible. A large and crucial segment of agriculture-related activities in the public sector – especially major irrigation and electricity – has to be managed as integrated, multi-tiered systems calling for specialised professional expertise. The organisational arrangements in such cases are necessarily more complex.

The inefficiency of existing arrangements in these two sectors is partly due to the strangle-hold governments have on their functioning and partly to their extremely rigid internal organisation, manned and run entirely by government bureaucracy. Being complex operations demanding high level of technical expertise a strong, professional management is of course essential. But as in most other public systems in India, there is much room for improving in the way activities are organised, co-ordinated, and monitored. Among various measures to this end, user participation in all phases of their management and decentralisation of decision-making as well as monitoring would stimulate greater efficiency.

In the case of power, the possibility of 'unbundling' generation, transmission, and distribution open up possibilities of handing over distribution to panchayats, co-operatives or even private enterprise. Experiments for encouraging competition in generation, with transmission grids being operated as a separate entity, are also under way in countries like the US. These developments point to options for the reorganisation of the electricity industry and its regulatory system.<sup>14</sup>

A more detailed blueprint of organisational reform for large irrigation works has been proposed by a committee of the Planning Commission. 15 It envisages that each system should be constituted into a separate entity wholly autonomous in respect of management and finance. The management will be in the hands of a professional bureaucracy answerable to a board comprising representatives of farmers in the command along with nominees of the government. Depending on the size of the system, management committees of similar composition could be constituted at the intermediate levels. Tertiary facilities are to be vested entirely with users served by each outlet.

It is envisaged that user representatives will be fully involved in formulating (or modifying) the rules as well as implementing them. The system management defines the allocation rules and procedures. Subject to these, the system managers contract to supply specified quantities at designated times and for a specified charge. Each group would then be responsible for deciding the allocation

management, it not the creation, were as well as the revying and confecung charges entrusted to user communities or co-from individual users within its territory.

Under such an arrangement, the chances of evolving generally acceptable allocation rules and ensuring compliance will be greater than when these tasks are entrusted wholly to the state bureaucracy. Users' incentives to keep a watchful eye and exert pressures for efficiency in construction and subsequent management of the systems are likely to be stronger if they have a direct financial stake in their construction/improvement of the facilities. The committee therefore recommended that users should be required, in future, to contribute a sizeable part of the capital costs of new or improvement works.

Autonomy, decentralisation and user involvement are also germane principles for restructuring agricultural research, education and extension services. 16 The present system is far too centralised and rigid to adapt programmes to the varying needs and circumstances of different states and regions. Greater flexibility and encouragement of initiatives on the part of the state government and agricultural universities to correct this defect is one aspect of reform. Being in the nature of public goods, financial viability (judged by their ability to recover the cost of services rendered) is not an appropriate criterion of performance. Performance has to be judged more directly. But there is need for devising more meaningful indices of performance.

Measuring the output of research establishments in terms of the number of improved seed varieties released is quite unsatisfactory. A more meaningful index would be the rate at which they are pushing up the yield potential for different crops under different agro-climatic conditions (a good measure would be the maximum yield obtained by research stations on their experimental stations and in controlled trials on farmers' fields for different crops and under different agroclimatic and irrigation conditions); focusing on the behaviour of actual yields relative to the proven potentials and the extent of interaction between research system and extension workers/farmers and its role in shaping research programme; and periodic independent, professional evaluation of the performance of the research system and its constituents.

Similarly, in the case of extension services, the number of demonstrations conducted, the number of soil samples tested, or the number of farmers who sought and were given advice are not adequate measures of performance. Periodic sample surveys to assess the extent to which farmers in fact adopt the advice, and their opinions about the promptness and quality of advice received would provide a far better basis to asses the efficacy of the services, identify the weaknesses and corrective action.

### DECENTRALISATION

These activities, as indeed much of the planning for agriculture and rural development, suffer from over-centralisation. Under the Indian constitution, practically all aspects of agricultural and rural development fall within the domain of the states. Laws relating to land tenure, co-operatives, water resource development, forests and marketing are enacted by the state legislatures and implemented by the state governments. The public sector programmes for agriculture are supposed to be planned and implemented by the states. The centre's powers are limited to agricultural research, financial institutions and water resource development on interstate rivers. However, the centre has come to exercise - through party channels, through the Planning Commission and above all by virtue of its superior command over resources - influence states' programmes and priorities for agriculture over a much wider area.

The central government has, over the years, taken the lead in proposing new programmes in the field of agriculture and in funding them. In doing so the scope and content of agricultural programmes which are supposed to be exclusively in the domain of the states, are being increasingly shaped by the centre. The result has been a needless proliferation of programmes often involving duplication and waste. It also tends to impose on the states schemes of a uniform pattern, unmindful of the great diversity of conditions in the country. If this process is to be reversed; as it must, the states must give up their passive acquiescence of centrally sponsored schemes. They should be encouraged to take greater initiative to experiment, innovate and evolve strategies and programmes appropriate to their specific situations.

Local governments did not, until recently, have any constitutional status. Nor did they have much authority or resources to decide on the scale and content of local programmes. Practically all public sector projects under the state plans and their distribution between different districts are decided by the state government and implemented through the state bureaucracy. The situation, however, is expected to change significantly in the wake of the recent constitutional amendment for setting up elected local governments as the third tier of government.

Decentralisation is necessary not only from the centre to the states but also from the state to the local (district) levels. Agricultural and rural development programmes can be divided into two broad categories, namely, programmes (like research, major irrigation projects, river basin planning, afforestation of catchment) which have to be planned and implemented by the state or the central governments and those schemes (minor irrigation, roads, integrated micro-watershed development, elementary schools and the like) which are best implemented and managed locally.

Development schemes which are essentially local in character constitute perhaps as much as one-fifth of the public sector plan outlay in India. They offer much scope for simplification, rationalisation and decentralisation. In the first place, all programmes in this category (including all poverty alleviation, special area and crop programmes, programmes for vulnerable segments, rural development, basic health care and elementary education), could be pooled and divided into two broad categories: one for augmenting employment, productive capacity and incomes on a sustained basis and another to ensure that all people in all areas have access to a minimum standard of basic social amenities (schools, hospitals, water supply).

The total resources under the first category could be allocated among the states and through them to the individual districts in proportion to the number of poor and unemployed or some index which captures these magnitudes with reasonable accuracy. The resources for ensuring basic amenities could be distributed to districts through the states on the basis of the deficiency in the current level facilities available relative to the accepted minimum standard. The resources for the two categories of local programmes should be transferred to elected local governments leaving them free, with such technical help as they may need from the state and the central professionals, to decide the composition of the programme in the light of local conditions.

Once the constitutional provisions regarding mandatory elections to the local government are implemented, political accountability for the effective use of available funds will be substantially strengthened. This could be further reinforced over time by insisting that local governments supplement resources (in cash, kind or labour contributions) to finance such activities. They should also be given powers to determine their own manning policies. These steps together would help bring about a better match between programme content and local needs/possibilities, reduce the necessity for central monitoring and interference to ensure effective implementation and reinforce the incentive for local governments to make proper use of resources available to them.

### Conclusion

The purpose of this essay is to underscore the crucial importance of institutional reform, particularly in the domain of public systems, for sustained technical progress and output growth in agriculture. There is limited scope for privatising irrigation, research and extension, and other infrastructure facilities. All of these will continue to be mainly the responsibility of public sector. Unless the public sector's efficiency in mobilising resources and managing these facilities is vastly improved, trade and price policy reform will not make a significant difference to the pace of agricultural growth.

Specific ingredients of desirable reforms have been better studied and worked out in some areas than in others. For instance, we know more about what needs to be done in the case of surface irrigation than in the case of groundwater. The framework of laws and regulations in which institutions function and the mechanisms of public regulation in the context of agriculture are not as well studied. The articulation of a blueprint for reform will require further detailed studies. The burgeoning theoretical literature on transaction costs, incentive systems, principal-agent problems, enforcement mechanisms, collective action and other aspects of social and economic institutions provides a promising basis for this purpose.

An action blueprint must not only specify what is desirable but also a strategy for getting it accepted and implemented. Such a strategy has, by its very nature, to be political. Any disturbance of the existing arrangements, and the manner in which they function, affects some groups adversely, some favourably and some in a mixed way. Overcoming the resistence of those adversely affected by mobilising potential beneficiaries of the reform is often not easy, especially when they are large in number and not so well endowed in terms of resources. The necessary combination of a long term systemic vision, statesmanship and power is to be found rarely, if at all. More commonly, politicians and the bureaucracy, who play the key role in mediating the reform process, face precarious tenures and stand to lose as a result of reform and are unlikely to be enthusiastic about it. But they do act under pressure of extreme circumstances. The emergence of chronic and unsustainable fiscal imbalances at the centre and in the states is one such circumstance. This, together with the growing clamour from the users of facilities and services provided by the public sector, could be the basis for a political initiative to initiate urgently needed reforms.

### Notes

[This is revised version of a paper piepared during April-May 1995 as Visiting Fellow at the World Resource Institute, Washington, DC. Thanks are due to the WRI for enabling me to work on it without any distraction. The preparation of the paper, and its subsequent revision, has greatly benefited from discussions, comments and reactions from Robert Repetto, Francis Colaco, S Neclakantan, T N Srinivasan, C T Kurien and

responsibility applies Thanks are also due to P S Syamala for typing the paper.]

- 1 For a comprehensive review and critique of governments trade and pricing policies relating to agriculture from the liberalisation perspective see Gulati and Sharma (1991).
- 2 Nearly three decades back Dantwala drew attention to the paucity of empirical studies on aggregate supply response to price incentives. He further argued that the role of price policy as a determinant of agricultural growth was greatly exaggerated; and that non-price factors, especially technology and public investment in infrastructure, are far more important. His arguments remain valid even now [Dantwala 1967, 1976].
- 3 It is noteworthy that a recent conference on liberalisation and agriculture did not have any paper on agrarian structure and reform; nor, it seems, did it figure much in the discussion [see Bhalla 1994].
- 4 For a different viewpoint on this issue, see Indian Journal of Agricultural Economics, July-September 1991 and January-March 1992 (pp 28-30).
- 5 Co-operatives are of course not the only form of organisation based on collective action. There is growing interest in other forms of the community-based development and use of land, forests and common pool resources like water [e g, Moench 1993, Chopra 1990, Kothari 1996] There is also an extensive literature on the theory of collective action, the more well known contributions being that of Marcur Olson and Elinor Ostrom
- 6 For a comprehensive review of the rural credit system and co-operatives see Khusro (1988).
- These arguments for an active role as regulator and participant for the public sector are questioned on the grounds that it has proved to be inefficient and that the regulatory authority is liable to be captured and rendered ineffective. However, all public systems are not inefficient, inefficiency is not confined to them, nor is such inefficiency inherent or irremediable If public intervention is essential for social purposes, it is essential to focus on how the nature and modalities of such intervention and institutional arrangements in public systems can be made more effective.
- 8 For an overview of the current state of water laws in India see Singh (1991, 1992). This review covers only formal laws. The nature and basis of informal community regulations based on custom as well as the case law reflected in court judgments remain largely unanalysed.
- 9 These issues have not received adequate attention in the literature on irrigation institutions. For a review of this literature see Vaidyanathan (1986)
- 10 The legal and institutional prospects of ground water regulation have received some attention in recent years. They focus on the role of markets along with proper pricing of energy as an alternative to regulations [Shah 1993] and on the merits of social regulation by local communities [Moench 1993, Saleth 1996]. But the literature reflects inadequate appreciation of the inherent difficulties of defining enforceable property rights over groundwater [Vaidyanathan 1996].
- 11 See Singh (1986), Saxena (1995).

- organisations in irrigation see GOI 1992.
- 13 Public sector reform is a widely discussed subject. The need for ensuring autonomy and accountability has been emphasised by numerous committees of government and parliament, and in plan documents. But the fundamental issue of insulating managements of public undertakings from executive and political interference and devising mechanisms of accountability in such an arrangement are consistently evaded.
- 14 For a review of issues involved in relation to electricity see Hema (1996).
- 15 See GOI, Planning Commission (1992)
- 16 The ICAR was reviewed by a high-power committee in 1988 [Rao 1989] but the review was mostly limited to organisation, personnel and management. It did not come to grips with the problem of evolving meaningful measures of performance.

### A New Journal on Women's Studies

### The Journal of Women's Studies

A bi-annual journal of the Women's Studies Research Centre, Calcutta University, whose first issue has been just published, is a pioneer publication in its field, being the first of its kind to be released from an Indian University. This international and inte disciplinary journal is envisaged as a forum for analysis and debate on the cutting edge of the dynamic and developing discipline of Women's Studies.

# Economic Reforms, Employment and Poverty Trends and Options

### Abhijit Sen

If poverty reduction is to be a serious part of the agenda of economic reforms, the reforms will have to have an explicitly redistributive content. This will require cuts in subsidies to the rich and also higher taxes to maintain and increase the expenditure relevant for the poor. In addition, the old issues of land distribution and provision of universal primary education and health must be put back on the agenda.

But, more than anything else, it must be recognised that a reforms strategy which aims to withdraw the state from investment, liberalise finance and thus divert finances from the state to the private sector, liberalise agricultural rade and thus enrich the rich at the direct cost of the poor and seeks to control inflation and balance of payments problems through deflation and devaluation is at its root a fundamentally inequitous adventure.

HIS paper is concerned with the possible pact of the economic reforms undertaken the government of India in the 1990s on e nature and incidence of poverty in India. ne point of departure is the observation om NSS data that poverty, which had not owed any time trend at all till the mid-70s, declined significantly between the id-1970s and the end-1980 but appears to ive increased again in the 1990s. In other ords, poverty appears to have declined ity in the decade and a half beginning the id-1970s during which there was an plosion in public expenditure leading up the fiscal crisis which, among other things, ecipitated the economic reforms in 1991. us suggests that there might be a much ionger link between public expenditure id poverty reduction than is usually opreciated, and this in turn has the iplication that the reforms process may tually impinge adversely on the poor if its cus continues to be on the reduction of iblic expenditure.

For this reason it is important to identify e direct and indirect effects of public openditure, and of other aspects of the conomic reform policies, on poverty leviation. This paper is a very preliminary fort in this direction. In the first section, brief outline of the trends in and structure I poverty in India is presented, with a view identifying the important characteristics f the poor population. This allows for an stimation of the likely effects of such policies n the material condition of the poor and iose close to the poverty line. Since poverty found to be closely related to employment nd occupational characteristics, a discussion n past employment trends and poverty trends included in the next section. In the llowing section, there is a more detailed onsideration of the recent trends in poverty; ad this is followed by a section which deals pecifically with the statistical determinants 1 poverty as well as the relationship between is and economic growth. Finally, the last section sets out some brief conclusions in terms of different policy options for economic reform which make poverty reduction an explicit objective.

### I Long-term Trends and Profile of Poverty

The Economic Survey 1995-96 has claimed that "the percentage of India's population below the poverty line has declined from 25.94 per cent in 1987-88 to 18.96 per cent in 1993-94". This claim is based on estimates made by the Planning Commission using a methodology whereby the consumption distribution obtained from the National Sample Survey (NSS) are applied to total estimates of consumption expenditure as obtained from the Central Statistical Organisation's (CSO) compilation of National Accounts. On this basis, the rural poverty ratio declined from 28 37 per cent in 1987-88 to 21.68 per cent in 1993-94 while the urban poverty ratio fell from 16.82 per cent to 11.55 per cent. These figures, which have been used to claim that there has been no increase in poverty following the economic reforms initiated in 1991, have in turn been challenged by independent analysts. The criticism takes two forms. First, that even using the Planning Commission method, poverty in 1993-94 was higher than in 1990-91 just before reforms began and so the comparison with 1987-88, a drought year, gives a misleading trend. Second, and much more importantly. that the Planning Commission method is itself flawed as was pointed out in 1993 by the high-level Expert Group on Estimation of Proportion and Number of Poor. Using the methodology suggested by this expert group, not only are the poverty figures much higher, these show that there is no real trend decline in poverty since around 1986, that poverty increased massively between 1989-90 and 1992, and that although poverty fell in 1993-94 this was still higher than in the immediate pre-reform years 1989-90 or 1990-91.

Some of the issues which arise from these different estimates are discussed in a later section. Here, we need to outline the longterm trends in poverty, and for this we present in Table 1, estimates from a third source altogether - that compiled by the Poverty and Human Resources Division of the World Bank,2 also using NSS data. This source gives a long series from 1951 onwards, and the main message which emerges is important. This is that there was no longterm time trend in poverty from 1950-51 to 1973-74 by that there was thereafter a sharp decline in poverty till 1986-87. After 1986-87, the decline continued at a slower pace till 1989-90 when it was reversed, with a particularly sharp increase in poverty in 1992. Poverty declined again in 1993-94 so that rural poverty in 1993-94 although higher than in 1989-90 or 1990-91 just before the reforms, was at about the same level as in 1986-87. Urban poverty, which had not increased particularly in 1992, was, however, lower in 1993-94 than in any pre-reform

These trends are important for a number of reasons. First, the trend in rural poverty shows a very close similarity with trends in agricultural wages. Estimates of real agricultural wages from a number of sources also show stagnation till the mid-1970s with sharp increases thereafter till the end-1980s when there is a slow-down again. Second, the period of declining poverty (mid-1970) to end-1980) was relatively short, and one which was marked by increasing government expenditure leading to severe fiscal imbalances by 1990. Third, that this period of declining poverty was infact one when rural poverty declined faster than urban poverty. Fourth, that rural poverty stopped talling, and indeed increased, as soon as fiscal stabilisation was attempted after 1991, and during this latest period the gap between increase. These trends require explanation and analysis, and this is the main focus of this paper. In the remaining part of this section, we provide a brief outline of the profile of Indian poverty.<sup>3</sup>

The most comprehensive data on the structure of poverty remains the information that can be gleaned from the NSS large sample survey of 1987-88, since details of the more recent large sample survey conducted in 1993-94 are not yet available. It seems reasonable to assume that in broad contours the picture that emerges for 1987-88 remains valid for the early 1990s.

Some of the evidence on the structure of poverty in India in 1987-88 is provided in Table 2. The first and most obvious point to be made relates to the dominantly rural nature of the poor population. The poor in rural areas constituted around three-fourths of the total poor population. This has to be juxtaposed with the fact that subsequently urban poverty has declined at a faster rate, so that poverty has become even more rural in nature. Within the rural areas, there is also evidence of greater regional concentration of poverty, with some backward regions displaying a very high incidence of poverty as discussed below.

In the rural areas at an all-India level, the worst off economic group is that of rural labour, both agricultural and nonagricultural. This is true both in terms of depth of poverty and its severity in terms of distance of average incomes from the actual poverty line. Within this broad category of rural labour, casual labour on non-permanent contracts is the most susceptible to absolute poverty. There is no discernible difference in poverty ratios between agricultural and non-agricultural casual labourers, which is not surprising, since the casual labour populations tends to move between agricultural and nonagricultural occupations as they become available The self-employed rural households, whether agricultural or nonagricultural, tend to experience much lower levels of economic deprivation than other rural groups.

Female-headed rural households recorded a higher than average incidence of poverty, both in terms of prevalence and severity. Those rural households classified as poor tended to have higher than average representation of adult females and lower than average representation of adult males. Also, poor households in general tended to have higher dependency ratios, so that children dominated in the number of poor persons, and were over-represented in the poor population relative to the total population. Also, there are definite social dimensions to material deprivation, with the category of scheduled castes and scheduled

of poverty than the general rural population. In fact, scheduled tribe groups are even worse off than scheduled castes on average, and tend to be the most economically destitute of all the rural population.

The urban areas present a slightly different picture. Firstly, the poor are more economically and socially heterogenous. Thus, the most important occupational groups among the poor urban population are those employed in casual labour, as well as a section of the self-employed. The selfemployed category is highly heterogenous in urban areas, comprising both highly paid professional occupations as well as informal sector low paying activities. The latter constitutes among the poorest of the urban population, along with workers employed in insecure casual contracts. Clearly, the irregular and insecure nature of such incomes, which are also typically low, is the major source of poverty in urban households. Scheduled castes and tribes were less significant among the poor in urban areas than in rural ones, and there was no real poverty. However, the problem of poverty among female-headed households was far more serious in the urban areas. Despite this, the dependency ratio among poor urban households was slightly lower than among their urban counterparts.

In terms of regional concentration of poverty, only two states - Bihar and Uttar Pradesh - together accounted for 34 per cent of the total poor population in 1987-88. In Bihar in particular, there was a large overrepresentation of poor people, and there is no reason to believe that this has altered dramatically. Another six states - Andhir Pradesh, Madhya Pradesh, Maharashitar Orissa, Tamil Nadu and West Bengal accounted for a further 43 per cent of the poor. For rural poverty in particular, there was over-representation of the poor in Madhya Pradesh, Maharashtra, Orissa and Tamil Nadu. In the states of Gujarat, Rajasthan and Orissa, scheduled castes and tribes accounted for more than half of the poor well above their share in total population. Scheduled tribes, especially in these states,<sup>†</sup>

Notes: H: head count ratio of poverty; PG poverty gap ratio; SPG: squared poverty gap.

Source: B Ozler, G Dutt and M Ravallion, 'A Database on Poverty and Growth in India', The World Bank, January 1996, for estimates up to the 48th round; For 50th round, NSS data has been used to calculate the estimates using exactly the same methodology as in the rest of the series.

re round to be among the most absolutely rived and destitute of all Indians.

here is a close relationship between the rent of poverty and patterns of employment dreal wages. In the rural areas in particular argued in the section below – two factors. critical (in addition to food prices) in taining the incidence of poverty bother time and across states and regions: the haviour of employment including the gree of diversification away from purely icultural employment, and movements in all wages. For this reason, trends in the hand pattern of employment are very antindicators of the extent and severity poverty.

### II Trends after Mid-1970s

The essential point which emerges from previous section is that a sustained decline poverty is observable only after 1973-74, I that thus process was over by 1990-91. Tact, the decline was almost certainly a nomenon which began after 1975-76. The years 1972-75 were difficult years with inflation was low growth, and the prin poverty in 1977-78 as compared 1973-74 is to a large extent attributable the comparison of an excellent agricultural rewith a year when output was belowed. For this reason it is more reasonable late the beginning of the poverty decline around 1977-78.

As is well known by now, during the 10d 1977-91 (and particularly during the ')s) the Indian economy underwent a umption-led boom, spuried on by increaevenue deficits of the government, and ced in large part by high deficits on the nal current account. This is the boom th went bust in 1991, laying the basis reforms'. But since this boom and bust te is paralleled fairly closely by what pened to rural poverty, it is worth ounting some of its more important teatures. First, the boom was possible at all ise, with increased access to external and with agricultural growth higher the long-term average, the Indian my was much better placed on the y side, with both of her two traditional y constraints greatly eased.

ond, during this boom it was the nised sectors of the economy which, fastest in terms of incomes and output, withis growth did not lead to much increase in organised sector employment. The rate of sowth of organised sector employment be lerated significantly, and the 1980s of the foundation of the propulation growth. Within this, employment in the private organised sector was the most sluggish, averaging a growth rate of only

0.2 per cent per annum, and there was slow growth also of employment provided by the Central government and its industrial undertakings. In fact, whatever employment growth occurred in the organised sector was provided mainly by state governments and certain quasi-government organisations, for example the nationalised banks. Moreover, during this period there was also a sharp drop in labour absorption by the agricultural sector, and agricultural employment also grew at a rate substantially below the rate of population growth, and below rates of growth achieved in the past at times of lower output growth. Thus, the rapid growth of output in agriculture and in the organised private sector failed to translate itself into higher direct employment in these important

Nonetheless, and this is the third important point, this decade was characterised by rising real wages and a fairly sharp drop in both the incidence and the severity of poverty, particularly in rural India. According to calculations made for this paper, using data from the National Sample Survey and following the methodology recommended by the Expert Group on Estimation of Propotion and Number of Poor, there was a steady decline in the head count measure of poverty for the rural population from 56.4 in 1973-74 to 53 1 per cent in 1977-78 to 45.6 in 1983, 38.3 in 1986-87 and to 37.9 per cent in 1989-90.4 The urban poverty ratio similarly fell steadily from 49.2 per cent to 32.4 per cent during the same period. This meant that the incidence of poverty which had fluctuated, positively with inflation and negatively with agricultural output, with if anything a positive underlying trend up to the mid-1970s began to decline thereafter. The most important reason for this was the fact that real wages of unskilled labour increased significantly in both urban and rural areas. Several alternative sources of data are available for agricultural wages, and all of these suggest that real agricultural wages increased by around 50 per cent during the decade – an increase almost double the increase in labour productivity in agriculture during this period.

These observations indicate that there were important changes in the nature of intersectoral and other linkages in the economy. One important point is that, although agriculture continues to be the largest employer of the workforce and productivity increases here are of major weight in the economy, the rest of the Indian economy appears to have become progressively less dependent on the behaviour of agricultural output during the 1980s. This is evident from the fact that the period of relative stagnation in agricultural output 1983-87 was nevertheless marked by high growth rates in non-agriculture, and, more generally, econometric evidence suggests that the earlier dependence of aggregate economic growth on the behaviour of the monsoon seems to have diminished. There are three major reasons for this. First, the sharp decline in the employment elasticity of output of the organised sectors of the economy meant that increased output in industry and services today involves a much lower concomitant increase in the demand for wage goods.

based industries fell sharply so that agricultural raw materials played a less significant role as industrial inputs than earlier. The boom sectors of the 1980s – chemicals, consumer durables and high-tech services – had very little linkage to agriculture. Thirdly, the combination of an easier import situation and an enhancement of government operations meant that government policy instruments were more effective in insulating the non-agricultural sector from the effects of monsoon fluctuations.

This last, i.e., government policy, operated on both the supply and demand sides. Given its higher foodgrain stocks and easier access to foreign debt, the government could better ensure agricultural supplies to nonagriculture during periods of low agricultural output by running down its stocks and by resorting to higher imports of other agricultural commodities. And, the demand consequences on non-agriculture of lower agricultural incomes during such periods were also better mitigated because, at such times, the government stepped up its revenue expenditure in rural areas, by expanding employment programmes and by generating more self-employment opportunities either directly through its own rural development schemes and/or by instructing banks to extend more credit. Thus, although there were features in the nature of organised sector growth which tended to weaken agriculturenonagriculture linkages, the extent of this weakening depended considerably on a particular type of government involvement. Because of this, the continuing importance of agriculture cannot be wished away easily, since a fall in agricultural output can still have severe negative implications for the economy, both in terms of output and inflation.

Indeed, what is striking about the experience of the 1980s is that despite the declining dependence of non-agricultural sectors on the performance of agriculture, the prices of agricultural goods rose faster than the general price level. This meant a reversal of the earlier terms of trade movement against agriculture, and this also went against the international trend of a worldwide movement of terms of trade against agriculture. That this increase in agricultural prices did not have unbearable inflationary implication was partly because of the tendency described above of weakened inter-sectoral linkages, and partly because of the way the food procurement and public distribution systems functioned. Government procurement of foodgrains was more than adequate and government stocks generally sufficient, the procurement prices were typically close to the market prices and domestic tood prices were also not too far speculative pressures, and the PDS, along with the government's free market operations, worked to some extent to keep the prices of essential foodgrains under control.

In fact, from the point of view of poverty, an important trend during this period was that while agricultural prices as a whole increased faster than the general price level, cereals prices increased slower, so that it was possible for real wages to rise without increasing product wages correspondingly. This was an important contributory factor behind the decline in poverty which occurred during the period. As will be discussed later, these equations appear to have changed in the post-reform period.

Moreover, there was another important development concerning linkages in the economy. This was the rapid growth of nonagricultural employment in rural areas. After a long period during which agriculture's share in the labour force had remained constant, there seems to have been a change somewhere in the mid-1970s when this share began to decline. Since the urban population has grown faster than total population, this is of course related to some extent with urbanisation. But it is important to note that during the 1980s, the pace of urbanisation was in fact less than in any decade since independence. For this reason it may be said that the really important development was the growth of the rural non-agricultural sector.

According to NSS surveys, the share of agricultural workers among all male rural workers declined steadily from 80.6 per cent in 1977-78 to 77.5 per cent in 1983 to 74.5 per cent in 1987-88 to 71.7 per cent in 1989-90. For rural females this share dropped from 88.1 per cent in 1977-78 to 87.5 per cent in 1983 to 84.7 per cent in 1987-88 to 81.4 per cent in 1989-90. The true significance of this shift is probably better understood in incremental terms: these figures imply that non-agriculture absorbed about 70 per cent of the total increase in the rural work-force between 1977-78 and 1989-90. And this rapid growth of rural nonagricultural employment provides the main explanation for what would otherwise be a puzzle: how did agricultural wages rise and

rurar poverty rain during a period when employment in both agriculture and the organised sector was growing slower that population? That this development, rather than the somewhat faster growth of agricultural output during the 1980s, was the major driving force behind rising wages and declining poverty becomes clearer when it is noted that while agricultural growth was regionally diverse (with agricultural output per capita decreasing in many states), the rapid growth of rural non-agricultural employment was a phenomenon which occurred in almost every state in the country. and almost every state recorded rising rural real wages and falling rural poverty between 1977-78 and 1989-90. In other words, there is need to modify the conventional view among Indian economists that the main factors determining rural poverty are agricultural productivity and the rate of inflation. Although both these continue to be very important, the growth of rural nonagriculture has emerged as an additional crucial link from the mid-1970s onwards

What then explained this growth of rural non-agricultural employment? The Indian literature on the subject has been dominated by two debates. First, whether the growth of rural non-agricultural employment is a positive development at all, or is it simply a reflection of the fact that agricultural employment has been sluggish and certain non-agricultural activities have emerged as 'residual sectors'. Second, to the extent that the growth of rural non-agricultural employment is not a 'residual', is it driven by developments in agriculture or are the growth impulses external? The idea that non-agricultural employment is 'residual' is now somewhat discredited because not only are average wages seen to be higher in such employment than in agriculture, but, more importantly, because agricultural wages have increased as non-agricultural employment has grown suggesting that what is involved is a pull factor which tightens the agricultural labour market. Nonetheless, NSS data show that the actual picture is more complicated and suggests that 'distress' movement into non-agriculture has continued to be important for a significant section of rural workers, as well as that the main dynamic source of rural

employment generation over this period has been the external agency of the state rather than forces internal to the rural economy.

There are several planks to this argument. Within agriculture, all the available evidence points to the decreasing ability of agriculture to absorb more labour, as the overall crude clasticities of employment to output are seen to be low in other major states and on an all-Indiabasis. However, there are substantial variations across states, with the agriculturally less advanced regions showing much higher elasticities than the developed states like Punjab and Harvana. Since some of the less advanced states (such as West Bengal and Bihar) actually showed the highest rates of output growth over the period, there was less of a dampening effect on the overall elasticity as well as a pointer to the importance of regional spread of agricultural growth for employment generation Moreover, an interesting observation relates to the flow of person day employment in agriculture, which, after 1977-78, was seen to be increasing more than stock measures of usual or weekly status workers. In a very rough and approximate sense, this suggests that the supply of agricultural labour (as measured by the stock of agricultural workers) was actually increasing slower than the demand for agricultural labour measured in person-days. Simultaneously there appear to have been contractual changes under way in agriculture, with a greater emphasis on casual contracts.

The natural question consequent upon such a finding is what caused the slow growth in the stock measures of workers in agriculture. Here it was found that pull factors out of agriculture were significant. The relationship between agricultural prosperity and the growth of non-agricultural opportunities was found to be weak and nonlinear, being significant only in states such as Punjab and Haryana where not only have agricultural incomes crossed a threshold but where further increases in agricultural output are accompanied by labour displacement rather than absorption. Outside this limited region, the pull is provided mainly by external stimuli. In certain regions, for example along the Bombay-New Delhi and the Bombay-Bangalore highways, there is clear evidence that industrial development, and the growth of services linked to this, have made deep inroads into rural society creating opportunities not only in the tertiary sector but also in small-scale industry. In addition, in the hinterland of industrially or commercially developed regions, there is growing incidence of workers who live in iural areas but commute to urban areas - a endency which has been enhanced by the iact that the organised sector has tended to prefer casual workers to regular employees, and because rising urban rents and falling transport costs have influenced workers' choice of residence. However, given the limited geographical spread of such direct links to modern industry and commerce, in most areas the pivotal role in the expansion of rural non-agricultural employment appears to have been played by the expansion of government expenditure.

As noted earlier, the 1980s were a period when, along with a rapid increase in all sorts of subsidies and transfers to households from government, there was a very large increase in revenue (as opposed to capital) expenditure on agriculture by state and central governments, and this was also a period when the expenditure on Rural Development expanded manifold. More generally, throughout the period political developments tended to give rural interests greater power and they were able to command an improvement in the historically low share of government expenditure benefiting rural areas. Although this improvement in share should not be exaggerated, an indication may be had from the fact that nearly 60 per cent of all new government jobs created accrued to rural areas during the decade. Moreover, NSS data suggest that, despite a low average contribution of only around 5 per cent of total rural employment, the government's contribution was around a fifth when it comes to either total rural nonagricultural employment in 1987-88 or the increments in total rural employment between 1977-78 and 1987-88. Moreover, in 1987-88. about 60 per cent of the regular nonagricultural employees in rural areas were employed by the government which created almost 80 per cent of the increments in such regular jobs during the decade covered.

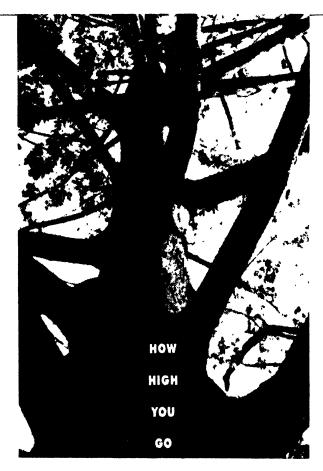

Thus, given the magnitude of what is now commonly accepted to have been a profligate growth of government expenditure, the total quantum of increased flow of public resources into rural areas must have been significant. Besides the large growth in agricultural subsidies already mentioned, this flow of resources took two predominant forms. There was, first, a fairly large expansion of 'rural

development' schemes with an explicit redistributive concern.6 This included not only the various rural employment and IRDP programmes but also a plethora of special schemes for a variety of identifiable 'target' groups. Motivated by the realisation that income growth by itself would not 'trickle down' in adequate amounts, these programmes were however less than entirely successful. They spawned a large bureaucracy and they became a focal point for the politics of 'distributive coalitions'. Yet, though the intended beneficiaries often got short-changed because of such leakages, these programmes represented a fairly massive net transfer to rural areas. The second avenue by which resources flowed from government to rural areas was through the greater accessibility of the rural elites to the government's normal gravy train. In part this was a result of greater mobility due to better infrastructure, but to a large extent it was also the outcome of the fact that with governments changing frequently (particularly at the state level) more new favours, not just jobs, but also various types of agencies and contracts, had to be distributed more often and the rural areas got a greater share in such electorally motivated largesse than they get at other times. The resulting flow of resources and the resulting generation of rural demand led to growing opportunities for diversification of the self-employed from agriculture to non-agriculture.

To a very large extent, the direct access to government permanent employment and also to many of the other resources was confined to the better-off and more powerful groups in rural society, to whom such incomes were more lucrative than agriculture. Associated with this was a large and significant increase in the proportion of the 15 to 29 age cohort which continued in education rather than join the work force. In part this must have been a result of the expansion of educational facilities as part of the general expansion of government in rural and semi-urban areas, but to a sub-

motivational change (to acquire necessary qualifications for a regular non-agricultural job) among the youth in the relatively well-off sections of rural society. There was thus a movement out of agricultural work at the margin by workers and potential workers from such better-off rural groups, which meant that sections of the relatively rich vacated agriculture either to obtain regular employment, mainly in the service sector, or to take up non-agricultural self-employment.

This increased the ability of members of the less well-off rural households to find agricultural work, and also created a demand for certain types of rural services and industry. The relative tightening in the agricultural labour market which resulted, helps to account for the increase in real wages observed from the late 1970s. However, although such increases in employment and wages did improve the condition of the poorest rural workers, their employment diversification into non-agriculture continued to have many characteristics of a 'distress' process, given the overall tendency of labour use in agriculture. Dictated by the need to ensure economic survival, they increasingly entered into casual work not only in agriculture but also in nonagriculture. The main sectors providing this type of non-agricultural employment were secondary sectors like construction, mining, and small-scale manufacturing, and there is evidence that over time the incidence of poverty among those employed in some of these sectors became larger than in agriculture Moreover, the agency of the state was important in terms of the diversification of opportunities for the rural poor. Thus, 22.3 per cent of all casual labour days spent on non-agricultural activity in 1987-88 were on public works programmes of the government, this percentage having increased from 17.7 in 1977-78 and 14.9 in 1983. And, although there is little evidence of any increase in non-agricultural selfemployment among the bottom 40 per cent of the rural population (such increase was largely among relatively richer households), income generation scheme such as the IRDP, must also have had some effect.

This is of course an extremely schematic presentation of what is a much more multifarious and regionally diverse scenario, and there were variations in the pattern across states and over time. However, the fact that the developments described above occurred in every state, irrespective of the rate of growth in agriculture or organised industry, does imply the increased importance of external stimuli to rural employment and, in particular, the crucial role of the state. More importantly, these trends mean that the rural labour demand is no longer determined only by what is happening within the

also by macro-economic processes and policies which do not at first appear to have any direct link with rural well-being.

Moreover, because much of the government spending involved is project funded, because most of the private enterprises involved are small and lack staying power, and because most of the wage employment thus created are casual, the vulnerability of the rural non-agricultural sector to overall public expenditure cuts and to restrictive monetary policy is almost certainly greater than for its urban counterpart. This has very important ramifications in the current macroeconomic context, in which the reform measures have particular implications for patterns of government expenditure as well as on internal and external trade.

It is important to note in this context that the pattern of structural adjustment and government economic strategy since 1991 has been one which has involved a continued stagnation in employment generation in the organised sector, both public and private. Moreover, this strategy involved.

- actual declines in Central government revenue expenditure on rural development (including agricultural programmes and rural employment and anti-poverty schemes), as well as on the fertiliser subsidy, in the budgets of 1991-92 and 1992-93. Some of these cuts were however reversed subsequently in 1993-94
- declines in public infrastructural and energy investments which affect the rural areas.
- (3) reduced transfers to state governments which have been facing a major financial crunch and have therefore been forced to cut back their own spending, particularly on social expenditure such as on education and on health and sanitation.
- (4) reduced spread and rising prices of the public distribution system for food.
- (5) financial liberalisation measures which have effectively reduced the availability of credit, especially to small borrowers particularly agriculturists.

rnus, in the early 1990s, there was a reversal of several of the public policies which contributed to more employment and less poverty in the rural areas in the earlier decade. It should, therefore, not be entirely surprising that rural non-agricultural employment appears to have declined fairly sharply as soon as the stabilisation and structural adjustment policies were put into place in 1991. According to NSS survey data, the non-agricultural proportion among rutal male workers was 28.3 per cent in 1989-90 and 29 per cent in 1990-91, before the reforms, and this fell to 25.1 per cent in July-December 1991 and 24.3 per cent in 1992. For rural female workers, the corresponding figures were 18.6, 15.1, 13.7 and 13 8 per cent. This represents a decline of somewhere between 9 and 11 million in the number of workers in rural nonagriculture, or a drop of 13-15 percent in the first 18 months of the initiation of the reform process 7

This fall occurred almost all over India, with only Karnataka and Madhya Pradesh being significant exceptions. In terms of sectors, this decline in employment was divided roughly equally between manufacturing, construction and community and other services, along with a smaller drop in transport; while mining, electricity, trade and financial services were immune among the self-employed and casual workers that the decline was greatest, with regular employment being largely maintained, except for some drop among regular male employees in the tertiary sector. Thus, the pattern of the decline in rural non-agricultural work suggests that it occurred not because of any large-scale retrenchment of regular employees by the government or the organised private sector, but because of a cut back in activity in the unorganised sector and, possibly, some retrenchment of casual workers by the organised sector. In this context, it is significant that, according to the NSS, this drop in rural non-agricultural employment was not accompanied by a corresponding drop of such employment

Notes: \* Denotes small sample, Poverty measures are same as in Table 1

workers this did not lead to any large increase in open unemployment or to any large fall in the work participation rate. Rather, the self-employed and the casual workers displaced from non-agriculture appear to have reverted back to agriculture, leading to disguised (rather than open) unemployment. However, as a result, real agricultural valueadded per agricultural worker dropped significantly, by over 8 per cent, even if comparison is restricted to the years 1989-90 and 1992-93 when monsoon conditions were very similar. Unfortunately, later data (particularly from the 1993-94 NSS large sample) is not yet available to verify whether this reversal of trend has continued, but clearly the early post-reform impact was adverse.

In the urban areas, regular employment has continued to stagnate, especially in the organised sector. During 1991-95, the growth rate of employment in the organised sector halved from its already low growth rate during the 1980s to only 0.8 per cent per annum, mainly because of a massive slowing down of employment growth in the public sector. The increases in employment that are discernible are essentially in casual employment, and this is evident for the secondary and tertiary sectors according to both usual and weekly status definitions. However, these increases in employment are still below the estimated increases in urban population over this period. The continued process of casualisation of work in urban areas has to be seen in relation to two other recent tendencies which are highlighted by several micro-level studies. First, there is the growth of subcontracting in manufacturing, which increasingly integrates formal and informal sector productive activities, and allows for a substantial part of the production to be undertaken by very small informal and unorganised units at the bottom of the production chain. These imply that a growing part of manufacturing production is formal protection of any sort to labour. Second, and related to the first tendency, there is evidence of some 'feminisation' of employment, that is the growing share of female employment to the total, particularly in export-oriented activities, and with wages and working conditions that are typically inferior to those of male counterpart workers.

It is evident that these processes will have direct and indirect links to the spread of poverty, throughout India but especially in rural areas. These links, and the more general relation between economic growth and poverty, are considered below.

# III Post-reform Trend in Poverty

In earlier sections it has been observed that there was a declining trend in poverty after the mid-1970s but that this trend was reversed in the 1990s. However, while the earlier declining trend is officially accepted, the reversal during the 1990s is not. As discussed earlier, the main difference between the official view and those of independent observers arises because till now the official estimate is based not on the NSS data directly but on adjusted figures obtained by blowing up the NSS consumption estimates for every decile group by a common adjustment factor equal to the ratio between the CSO estimate of private consumption and the corresponding NSS estimate. Because this adjustment factor has increased sharply in recent years, the official estimate has diverged increasingly from any estimate based directly on NSS data. The Expert Group which recently went into this matter concluded quite categorically that the practice of 'adjusting' NSS data was arbitrary and was likely to give wrong results because as against the implicit assumption in the official method that any underestimation of consumption is distributed uniformly over the entire population, it is better to assume who are non-poor.

In fact, several alternative series which use the unadjusted NSS figures are available. In addition to the World Bank series given earlier, a series calculated by Tendulkar and Jain is available for the period 1970-92.x This uses the same reference poverty lines at 1973-74 prices as the official and World Bank series, but using a different deflator they obtain an even larger increase in poverty between 1990-91 and 1992 (Table 6). In addition, it has been possible to obtain measures of rural poverty for All India and the major states, based on the Expert Group Method using NSS data covering the years from 1972-73 to 1993-949 (Table 7). Unlike the other series this is not obtained from the national-level NSS data but is obtained by applying state-specific poverty lines to state level NSS data. It must be noted that the figures given here for 1993-94 are preliminary, being based only on partial data (not yet officially released) from the 50th round of the NSS. Moreover, the data for 1986-87 and for 1989-90 to 1992 are based on the so-called 'thin' surveys by the NSS involving a much lower sample size than the other survey points. With only three survey points available for the post-reform period. and given the above qualifications for whatever data is available, any conclusion about post-reform trends must necessarily be rather tentative.

Nonetheless, using the mutually comparable thin samples alone, it is evident that poverty increased sharply during the first 18 months of the reform period (i.e., the second half of 1991 and 1992), particularly in the rural areas. The partial data relating to 1993-94 suggests, however, that this upward trend was reversed thereafter. Taken together, these data suggest that there was a very large increase in rural poverty in the first 18 months of reform but that this trend has been moderated, thereafter. Rural poverty in 1993-94 continued to be higher than in

| Tamil Nadu     | 57.4    | 57.7    | 54.0        | 41 2    | 45.8    | 38 4    | 37.5    | 44.3 | 32.6    |
| Uttar Pradesh  | 56.5    | 47.6    | 46.5        | 36.6    | 41 1    | 30.5    | 34.8    | 47 9 | 42.6    |
| West Bengal    | 73 2    | 68.3    | 63.1        | 47.3    | 48.3    | 37.2    | 49.5    | 44.0 | 40.3    |
| All India      | 56 4    | 53.1    | 45.6        | 38.3    | 39.1    | 34.4    | 35.0    | 44.0 | 37.5    |

1989-90 and 1990-91 but was less than in 1987-88. Urban poverty, on the other hand, appears not to have increased much during the first 18 months of the reform period and, indeed, appears to have declined significantly in 1993-94. Nonetheless, there were about 30 million more people in poverty in the latter year than before the reforms began. 10

Thus, the post-reform trends in poverty do not suggest either an unambiguous improvement or an unambiguous worsening. They do suggest, however, that the initial impact of the stabilisation/structural adjustment package was adverse, that this impinged particularly on the rural sector, with less impact on the urban sector, and that there was some general reversal of the adverse trend subsequently. Nonetheless, it is important to note that the state-wise figures show that, as far as rural poverty is concerned, in most states the poverty ratios in 1993-94 were significantly larger than in the immediate pre-reform period. This is particularly true of the two largest Indian states, Uttar Pradesh and Bihar, and also of the hitherto successful 'green-revolution' states of Haryana and Punjab. The exceptions are the Southern states of Andhra Pradesh. Karnataka, Kerala and Tamil Nadu in all of which the poverty ratio in 1993-94 was lower than in the immediate pre-reform period. However, it must be noted that in these states, and in Maharashtra and Gujarat, the year 1993-94 was exceptional in that the tood prices actually fell in absolute terms as against rapid increases in both preceding and following years. For this reason, the calculated poverty ratios for 1993-94 are likely to be somewhat lower than the underlying trend.

More importantly, these trends in poverty need to be viewed in the general context, discussed earlier, that the stabilisation and stuctural adjustment policies carried out so far in India involved a fairly sharp contraction in fiscal and monetary policy in 1991-92 and 1992-93, followed by a return to high fiscal deficits from 1993-94 onwards. The revival of growth after an initial period of stagnation also followed a pattern broadly coincident with that of the government's fiscal stance, so that both the initial worsening of the poverty situation and the subsequent improvement seem to be broadly in line with the overall growth performance of the economy. Yet, there are a few surprises, the most important of which is that although the reform measures did not directly involve much changes in agriculture, it was rural poverty which appears to have been more sensitively affected by the post-reform developments.

This has led some analysts, for example Fendulkar and Jain (along with many other conomists who are generally in support of the reform process), to argue that, although

poverty did increase during the first 18 months of reform, the reforms were not the principal cause for this increase. This argument rests on the observation that "the rural sector in general and agriculture in particular were not the major focus of structural adjustment and were only indirectly affected by fiscal compression" and on the assumption that the reforms "would have adversely affected primarily the urban organised sector with second-order impact on the urban informal sector and weaker effect on the rural sector". Because, in fact, it was rural poverty which increased sharply, they attribute this increase not to reforms per se but to weather and to the higher postreforms inflation for which, moreover, they hold the reforms only indirectly responsible. However, although the reform process has indeed neglected agriculture, there are two major difficulties with the argument that, therefore, it could not have increased rural

First, although there was a 2 per cent drop in agricultural production in 1991-92 compared to 1990-91, and although the inflation rate did increase sharply (particularly for foodgrains), these adverse factors were simply not large enough to explain the very large increase in the incidence of rural poverty. As discussed in the next section any econometric model fitted to the data prior to reforms linking the incidence of rural poverty only to some measure of agricultural production or productivity and to the inflation effect, breaks down as soon as the post-reform data is included. And, indeed, all such models are outperformed by models incorporating relative food price, rural non-agricultural employment and some measure of commercialisation, in addition to agricultural production. The latter not only fit the prereform data better, but when fitted to prereform data accurately track the post-reform increase in poverty, unlike models not including government expenditure and/or rural non-agricultural employment which predict much lower poverty increase than that which took place actually.

The important point to note is that this phenomenon of rural non-agricultural employment, which Tendulkar and Jain ignore, was almost certainly the major factor which drove rural real wages up, and caused poverty to decline, during the 1980s. And, in turn, this was based largely on increasing government expenditure and on the availability of cheap credit to the small-scale sectors. As has been pointed out in a previous section, the onset of stabilisation and structural adjustment appears to have led to a rather quick and large decline in such rural non-agricultural employment, pushing millions of self-employed and casual rural non-agricultural workers back to agriculture, thus reducing per-worker incomes in agriculture. It appears, therefore, that just as the expansion of the 1980s involved a rapid increase in rural non-agricultural employment without any concommitant increase in organised sector employment, the stagnation in the first 18 months of reform saw a cutback in rural non-agricultural employment with not much effect on either organised sector or urban employment. This suggests that, contrary to popular opinion, the employment multipliers associated with the government's fiscal stance are larger for rural nonagriculture than for the urban or organised sectors. If this is accepted, the trend in the magnitude of employment decline and poverty increase are not surprising, particularly because, as noted earlier, the contractionary tendencies generally impinged much more adversely on smaller enterprises than on the corporate sector 11

In addition, it is obvious that the effect on poverty of the rather small decline in agricultural output in 1991-92 could have been mitigated if rural employment policies had been used effectively, as they were during 1987-88 a year of much larger decline in agricultural and foodgrains output than

TABLE 8 BASIC REGRESSION RESULTS ALL-INDIA DATA (Dependent Variable Is Log of Headcount Poverty Ratio)

Note: T values in parenthesis.

1991-92. Indeed, a state-wise analysis shows that between 1989-90 and 1992 rural poverty increased in every state except Kerala, i e, it increased even in those states (Haryana, Karnataka, Madhya Pradesh, Orissa, Punjab, Tamil Nadu, Uttar Pradesh and West Bengal) where the 1991-92 foodgrains output was higher than in 1989-90, thus indicating a rather weak link between the fall in output and the increase in poverty. Moreover, it is interesting to note that the largest post-reform increases in poverty were registered in the two states, Gujarat and Maharashtra, which were most enthusiastic about the reforms process. Here, there was a fall in foodgrains output in 1991-92 as in 1987-88, but, unlike in 1987-88, the state governments neglected rural employment and drought relief schemes

Secondly, although inflation is clearly important, Tendulkar and Jain are not entirely correct when they claim that the large rise in inflation (to over 25 per cent for the Consumer Price Index for Agricultural Labourers) during the first year of reforms was only indirectly related to the reform process. Their argument is that inflation occurred because crop output fell in a year when foodgrain stocks were low and the balance of payments position did not permit large imports; and because the government succumbed to rich farmer demands to increase procurement prices following the (necessary steps of) devaluation and cut in fertiliser subsidy.

In fact, because of a record harvest in 1990-91, public foodgrain stocks were high, over 21 million tonnes, when the government embarked on its reforms at the end of June 1991. And inflation accelerated principally because of the expectations set-off by devaluation and the impression given that all discrimination against exports of agricultural goods would be removed. 12 This led to an immediate speculative increase in private stocks, forcing the government to run down its own stocks faster, and also contemplate food imports. However, the decision on such imports was postponed till after the next harvest. And when this turned out to be somewhat less than expected, the government was faced not only with low stocks but also with low procurement because farmers withheld sales in the expectation that it would be politically and economically difficult for the government to justify imports at prices well above domestic free market prices which in turn were higher than the procurement prices. In the event, the government was forced to increase both its procurement prices massively (linking this with withdrawal of fertiliser subsidies) and also import wheat at prices higher than the increased procurement prices.

The entire problem was thus clearly driven by the fact that devaluation was linked

explicitly with the idea of removing trade discrimination against agricultural goods and, therefore, with a central tenet of the liberalisation argument. If this had been followed through fully, food prices would have risen much more than they actually did and farmers would have received more than what they allegedly obtained as a result of their political clout. In fact, prices began stabilising only when the government made it clear that not only would some export restrictions continue on foodgrains but also that it would continue with its earlier policy of importing foodgrain to stabilise domestic prices, even if this meant making a commercial loss. For this reason, it can be surmised that the inflationary problem could have been avoided to a large extent had devaluation been accompanied at the outset by an explicit policy of increasing the wedge between world and domestic prices through higher export duties and a definite announcement that canalised imports would continue. That it was not, and led to an inflationary spurt which was contained only when the government backtracked, is one among a number of instances of how fidelity to the liberalisation world-view was extremely costly in the short-run without being sustainable in the longer run.

Thus, the massive increase in rural poverty, by over 60 million people, in the first 18 months of reform was to a very large extent a direct result of the stabilisation-cumstructural adjustment policies. The later data, for 1993-94, which shows a moderation in poverty does not necesarily contradict this conclusion because, after all, public expenditure cuts were to a large extent restored (and so rural non-agricultural employment might have risen somewhat) and stability was returned to foodgrains markets by removing the expectation that Indian agricultural prices were to soon reach international levels. Thus, although nothing firm c in be said about employment trends till the full data from the 1993-94 survey is released, the decline in poverty appears only to confirm that changes in public expenditure levels and announcements regarding liberalisation of international trade in agricultural products have a large and quick impact on rural poverty.

#### IV Determinants of Poverty

This brief review of trends in poverty bring us to the central issue of this paper: that is how liberalisation and structural adjustment may be expected to affect the incidence of poverty. Given the limited data and the somewhat conflicting empirical trends reviewed above, the remaining discussion will focus on past discussions of the determinants of poverty in India, and how the conventional logic needs to be modified in the light of subsequent developments. Since the Indian literature is mainly on rural poverty, this discussion will also focus largely on the rural sector.

Past literature has tended to focus on two types of variables; some measure of agricultural output or productivity and some price variable. And past writings have debated both the relative significance of these variables, and, more importantly, their proper specification.13 Thus, although the level and growth of agricultural production per capita of rural population is obviously an important variable determining levels of welfare in a predominantly agricultural rural community, it is also obvious that such a relationship would be affected by whether agricultural growth is accompanied by increasing inequality and whether there are other sources of rural incomes. The link between poverty and prices is even more complex. For example, when Dharm Narain presented regression results showing that poverty was related positively with higher food prices, his specification was challenged because his use of the nominal food price as an explanatory variable ran counter to the prior, common to most economists, that what really matters are relative prices, and, that if absolute prices need to be incorporated, this should be done by considering the rate of inflation rather than the price level.

As far as the importance of agricultural output as a determinant of rural poverty is concerned, it is obvious that, unless the

TABLE 9 ALL INDIA RURAL POVERTY EQUATION

manner in which higher agricultural output is brought about is sharply inequalising, any increase in agricultural output per capita would tend to benefit most rural people. It is precisely the fear of the possible inequalising impact of the 'green revolution' which had triggered off early work on this area. But, by now, it may safely be conceded that although relative inequalities may have increased, the 'green revolution' certainly reduced the incidence of absolute rural poverty in the regions where it was successful. But, although proponents of the trickle down hypothesis may have proved more correct than the detractors in this matter, the really striking feature of the post green revolution period is that, nonetheless, there is a rather weak link across states between the rate of agricultural growth per capita and reductions in rural poverty.

The simple fact is that, with the green revolution limited in geographical coverage, most states in India did not record any significant increase in agricultural value-added per head of rural population during the 1970s and 1980s, although almost all of them recorded significant declines in poverty.

With poverty reduced even where agricultural output did not increase, there has thus been a reversal of the earlier apprehension that agricultural growth could occur without reducing poverty. But this very disassociation between poverty reduction and agricultural growth is a feature which merits more attention than has been given so far. For example, it is significant that, while early work on the subject invariably chose some measure of agricultural output per capita, some recent research finds agricultural output per hectare to be the measure of agricultural performance better correlated with poverty decline. 14 This measure has the advantage, for those persistent in viewing agricultural growth as the main engine for the reduction of rural poverty, that on this basis almost every region in India recorded some agricultural growth during the period when poverty declined, and, in most cases, this growth was also larger than during the earlier period when rural poverty did not decline.

Yet, given the stagnation of agricultural output per head in most parts of rural India, this shift in the measure used surely serves to obfuscate matters rather than to clarify them, especially because in actual fact the underlying shift in Indian agriculture from expansion of cropped area to yield increases has been accompanied by a sharp decline in the output elasticity of agriculture's demand for labour. As a result, poverty has declined in most regions of rural India in a context not only of stagnant agricultural output per head of rural population but also one where agricultural employment has grown much slower than the growth of the

rural labour force. This latter feature would normally be expected to depress agricultural wages and thus affect adversely the poorest among India's rural residents. But, in fact, real agricultural wages increased sharply in most parts of India between the mid-1970s and late 1980s, and this was, in fact, one of the main reasons why poverty declined.

Some researchers do note the rise in wages but chose to 'explain' this rise also by reference to the increase in output per acre. This, however, stretches credulity because by almost every measure the rise in real wages was at least twice as much as the increase in real output per worker, and cannot, therefore, be ascribed mainly to technical progress in agriculture. As has been argued already, the real explanation for the rise in agricultural wages hes in the rapid growth of rural non-agricultural employment and the dynamics behind this. The Indian literature on this has in the past toyed with two ideas; that rural non-agriculture is itself driven by agricultural growth through the operation of Engel's law; and the opposite idea that the process of commercialisation of agriculture leads to displacement of agricultural labour which finds distress employment in certain 'residual' sectors of non-agriculture. However, both these ideas are now somewhat discredited. The link between agricultural growth and that of rural non-agriculture has been found to be nonlinear, and, with the exception of the limited prime 'green revolution' area there is little evidence that agricultural growth has provided the impetus to rural non-agriculture Also, despite considerable evidence that commercialisation is inequalising and leads to casualisation of the rural labour force, the 'residual' sector hypothesis stands discredited because this does not square with rising real wages. The evidence overwhelmingly supports the thesis that the main impetus for the growth of rural nonagriculture has come from outside the rural areas, in considerable part from the expansion of government expenditure. This observation suggests that rural incomes are no longer derived only from agricultural production. and that the process by which rural areas have got integrated into the wider economy are important. One aspect of this has been commercialisation with its inequalising effects, but the other is that external stimulii

have provided employment opportunities and incomes which are related not so much with agriculture but with developments in the wider macro-economy.

However, many economists continue to view agricultural growth as the main solution to poverty. One reason for this is precisely because such an association fits neatly with the view that in countries like India, which protected industry in the past and therefore require 'structural adjustment' today, got it wrong not only on efficiency but also on equity. Indeed, during the 1970s, when the World Bank pushed its growth with redistribution slogan, the argument was that the pro-industry policies followed by countries such as India hampered agricultural growth and thus meant higher poverty than was necessary. Even today, some World Bank analysis tries to show that rural poverty is unaffected (or even worsened) by industrial growth while agricultural growth reduces not only rural but even urban poverty.18 This view continues to be a central component of the structural adjustment policies, wherein it is argued that greater liberalisation of trade and industry would shift resources towards agriculture and this would not only be more in line with India's comparative advantage but would also reduce poverty much more than earlier policies. In other words, although no one will dispute that higher agricultural output is very likely to reduce rural poverty, it is no accident that in circles where 'structural adjustment is seen as a good thing there is also an almost single-minded obsession with this causation, to the point of excluding from consideration other possible determinants of the incidence of poverty.

However, given Dharm Narain's critique of earlier work which concentrated only on agricultural output, these more recent analysts of rural poverty in India do not entirely forget the price dimension as a possible determinant of poverty. But, interestingly the focus in such recent analysis is almost entirely on how inflation is bad for the poor Thus, either an inflation term is added to agricultural output in statistical models explaining poverty or real wages are added as an explanatory variable to the poverty equation and an inflation term is added to the equation explaining real wages. The argument is the entirely plausible one that

TABLE 10: POOLED TIME SERIES AND CROSS SECTION ACROSS STATES (Dependent Variable Head Count Poverty Ratio)

| Constant                          | 5 3(9 61) | 5 8(16 59) |

| R Bar Squared                     | 0.87      | 0.88       |
| DW                                | 2 21      | 2 22       |

rural money wages (and possibly certain other components of rural income, such as the proceeds of the previous harvest) are not index-linked and therefore are not immediately protected against inflation, although these are likely to adjust in the longer-run.

But, although very plausible as an explanatory variable of short-run variations in poverty, the choice of inflation as the preferred price variable is again not entirely accidental. For reformers, this leads to the happy coincidence that while structural adjustment is good for poverty because that is likely to shift resources towards agriculture, stabilisation is also good for poverty because this will reduce inflation. Most importantly, this way of incorporating prices avoids facing the essential trade-off that Dharm Narain was pointing to: that between the possible beneficial effects of higher agricultural output on poverty and the possible losses involved if the preferred strategy for increasing agricultural output consists of higher agricultural prices

This is a trade-off particularly relevant for the structural adjustment policy as it relates to agriculture. As has been pointed out by many, this policy seems to have given no serious consideration to agriculture in terms of new programmes or investment, although it purports to be a virtual overhaul of the entire economy. But this is no accident either. In the liberatising worldview, most economic problems can be resolved by a greater recourse to markets and allowing the price mechanism 'tree' play. A similar position governs the attitude to agricultural growth, in that it is supposed that relative price movements and profitability ratios will be sufficient to ensure that supply responsiveness in agriculture will lead to higher rates of growth. And the critical variable here is the ratio of agricultural to other prices in the economy, which is sought to be increased by reducing trade protection to industry, through devaluation which makes non-traded goods cheaper relative to traded goods, and through removal of restriction on international trade in agricultural goods which would have the effect of increasing the domestic relative price of most agricultural products, including foodgrains.16

In other words, the very mechanism through which agricultural output is expected to increase under structural adjustment involves increasing the price of agricultural goods, notably food, relative to all other prices in the economy. This essential rise in the relative price of agricultural goods is thus not seen as a transient phenomenon like inflation, and it would leave the rural poor unaffected adversely only if the prices of goods and services they sell rises in line with the rise in price of food which makes up most of their consumption basket. The effect would

certainly be adverse if money wages are sticky. But, even with flexible wages and tull employment, wage workers would invariably lose if they got a substantial part of their income from non-agricultural activities in relation to which agricultural prices would require to rise. Unlike inflation whose control may be benign (if not accompanied by deflation), this essential relative price implication of structural adjustment is permanent by design and so also is its likely adverse effect on poverty. It is, therefore, noteworthy, and hardly accidental, that in the new set of poverty models, such a relative price variable is hardly ever included.

Moreover, deflationary policies designed to control overall inflation during a transition when domestic price relatives adjust to international levels may have a disproportionate adverse effect on the rural poor if the latter obtain sizeable parts of their income from non-agricultural activity. In Indian discussions on the subject, it is sometimes almost assumed that income and employment multipliers associated with fiscal and monetary policy never spill across municipal boundaries into rural areas. Nothing could actually be further from the

truth. With agricultural output determined from the supply side, and agricultural prices made inflexible downwards by government support operations, it may indeed be the case that the income multipliers of a deflationary package are borne entirely by nonagriculture. But given that most organised sector workers still have secure employment at pre-determined wage rates, the entire burden of the employment multiplier falls on the unorganised non-agricultural sector. This sector does not respect rural-urban boundaries and cut-backs in employment demand here are likely to have knock-on effects on the incomes of the rural poor: through a combination of lower nonagricultura' employment, falling real wages, and an increase in the extent of disguised unemployment in the agricultural sector.

That this latter effect might be important has already been indicated by the data so far presented on rural poverty and nonagricultural employment. Its plausibility is enhanced because much of the government spending which is important for rural areas is project or programme funded and thus more susceptible to expenditure cuts, because most rural non-agricultural enterprises are small and lack staying power, and because most of the wage employment thus created is casual. As a result, it would be no exaggeration to claim that the vulnerability of the rural non-agricultural sector to overall public expenditure cuts and to restrictive monetary policy is almost certainly greater than for its urban counterpart. This has very important ramifications in the current macroeconomic context.

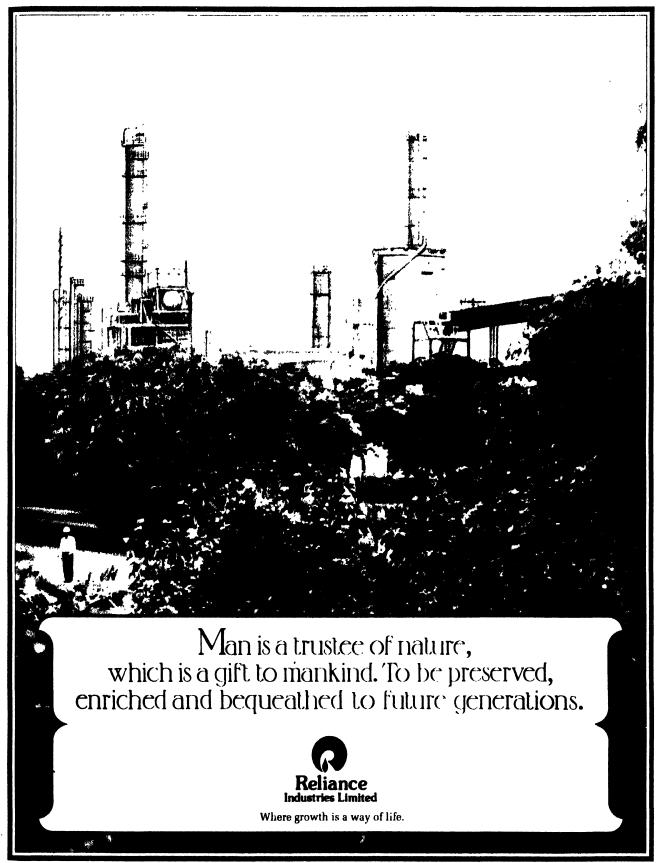

Thus, there are two possible stories which can be told about the impact of structural adjustment and stabilisation on rural poverty. The first is the benign one: that by increasing agricultural output and controlling inflation, these act to reduce poverty. Alternatively, there is the less optimistic but no less possible outcome that structural adjustment acts adversely on the poor because 'getting prices' right' leads invariably to a rise in the relative price of food, because greater reliance on market forces spurs inequalities inherent in the commercialisation process, and because these adverse effects are compounded by contracting non-agricultural employment and falling wages in the unorganised sector if the government wishes to contain, through contractionary stabilisation policies the inflationary fall out of adjustment.

Which of these actually transpires is an empirical matter, and one would expect economists to have tested for which of these effects are more likely. But oddly, the benign agricultural output/ inflation story of rural poverty seems to hold the fort without being tested seriously against the alternative hypothesis involving relative price changes, commercialisation, rural non-agricultural employment and the government's fiscal and monetary stance.

On the other hand, the discussion of actual developments earlier in this paper suggests that the simple agricultural outpu / inflation story about the determinants of rural poverty can be quite misleading. Thus, any explanation of falling rural poverty during the mid-1970s and 1980s would appear to be incomplete if it did not incorporate the fact of increasing rural non-agricultural

TABLE 11 DUTT-RAVALLION CROSS-SECTION AND TIME SPRIES POOLED (Dependent Variable Head Count Poverty Ratio)

INTERACT # VISION RILAVIS

employment and the role of government policy behind this. Similarly, our critique of the Tendulkar-Jain explanation of the increase in poverty post-reforms is also essentially that they fail to go beyond the agricultural output/ inflation story. In the remaining part of this section we attempt a statistical investigation.

To begin with, we regress head count measures of poverty for the period 1960-61 to 1993-94 at the all-India level in both urban and rural areas against per capita agricultural and non-agricultural incomes (with agricultural incomes defined per head of rural population and non-agricultural incomes defined per capita of total population). As the accompanying table 8 shows, both income variables are significantly negative in both rural and urban areas, and in both cases the agricultural income variable appears more important Next, the per capita non-agricultural income variable is split into per capita income from trade and transport (an indicator of commercialisation) and other non-agricultural incomes. The rationale for this is that many commentators (e.g., Vaidyanathan 1986) have argued commercialisation this tends to increase rural inequalities. In these respecified equations, agricultural incomes continue to be negatively related to poverty. but now there is a difference between the urban and rural equations. In urban areas, the commercialisation variable appears to reduce poverty while the remaining nonagricultural incomes have a positive effect. But exactly the opposite pattern appears in rural areas. Next, we include a public expenditure variable (development expenditure per capita, i e, government expenditure less interest payments and expenditure on defence and administration). This variable is strongly significant, reducing poverty in both rural and urban areas, with, interestingly, its coefficient almost double in rural as compared to urban areas. Moreover, on inclusion of this variable, the non-agricultural income variables become insignificant in urban areas, while in rural areas the earlier pattern is maintained.

These observations suggest a much more complex relationship between growth of nonagricultural incomes and poverty than usually appreciated As expected, commercialisation does indeed seem to be associated with increased rural inequalities, but it seems also to be associated with some increased opportunities for the urban poor. On the other hand, the expansion of other nonagricultural incomes appears to have reduced rural poverty while doing nothing to reduce urban poverty. This suggests that to the extent that the benefits of such income growth do percolate down to the poor, this spills over disproportionately to the tural sector, either because of rural-urban migration or because, as suggested earlier, employment multipliers are higher for rural non-agricultural employment. This latter suggestion finds some confirmation from the coefficients on the government expenditure variable, whose significance suggests also that such expenditure has a much larger impact on poverty than a general increase in non-agricultural output.

Surprisingly, on including an inflation term in these equations, this is found to have an insignificant effect on poverty in both rural and urban areas. Replacing the inflation term with a relative price variable (the relative price of cereals to all commodities in the wholesale price index) does however make a difference. This variable turns out to be highly significant in both areas, and also serves to reduce the significance of the public expenditure variable, which however continues to be significant.

These results need to be interpreted with caution because the mutual correlation between these explanatory variables is often high. But three points emerge quite strongly. First, that agricultural incomes are important not only for rural but also urban poverty. Second, that non-agricultural impulses, particularly public expenditure, are not only important but that they are especially so in the determination of rural poverty. Third, that, as far as the price variable is concerned, the relative price effect is if anything much more important than the effect of inflation per se.

Taken together, these results suggest that we need to modify the view that the principal determinants of poverty are agricultural output and inflation, and that, therefore, both structural adjustment and stabilisation are good. To consider this matter further, we replicated the version of this story as it emerges from the World Bank publication Growth and Poverty in India.17 This is more sophisticated than most other versions of the story in that it is a two-equation model whereby the incidence of rural poverty is 'explained' by the agricultural real wage and the lagged and current agricultural output per net sown acre. In addition the model includes the lagged dependent variable and a time trend. In turn, the level of the agricultural real wage is explained' in another equation by the inflation rate and the earlier agricultural output variable, in addition to a lagged wage term. In this model, therefore, higher agricultural output reduces the incidence of poverty both directly and through its positive effect on the wage rate; and inflation works on poverty only indirectly through the wage rate.

Table 9 gives the coefficients of the Ravallion-Dutt poverty equation obtained when fitted it to the periods 1960/61-1989/90 and 1960/61-1992 with all-India data. The first fit, which does not include the post-

•reform period, is almost the same as that reported in their original paper and appears to be a fairly good fit. However, the second fit, that of the same model fitted to data extended to the post-reform period shows that the model breaks down almost completely since the most important variable. agricultural output per acre, turns totally insignificant. Furthermore, the breakdown of the model occurs essentially because the magnitude of the actual increase in poverty is well beyond anything that this model can predict. In fact, when the model estimated with data up to 1987-88 is extrapolated, it is able to explain only a small part of the large actual increase in 1992, and also predicts an increase in poverty in 1993-94 as against an actual decline.18

This table also gives the details of an alternative model fitted to the same data incorporating our observations in the preceding discussion. Here in addition to the agricultural output and real wage variables we included the relative price of cereals, the proportion of non-agricultural workers in rural population and the commercialisation variable (the per capita GDP from trade and transport). An interesting observation is that on inclusion of these variables, the time trend and the lagged dependent variable used by Ravallion-Duttt turn insignificant, suggesting that in fact the adjustment of poverty to real factors is much faster than that suggested by the Ravallion-Dutt model. This alternative model not only fits past data much better than the Ravallion-Dutt version, but also, unlike theirs, remains robust when extended to the post-reform period. In parti-cular, the massive increase in rural poverty in 1992 is predicted with complete accuracy by the model fitted up to 1987-88.19

These results not only emphasise the importance of the relative price variable and of non-agricultural factors, they cast strong doubts on the simple agricultural output/ inflation paradigm. This paradigm is further compromised because it is seen that the wage equation in the Ravallion-Dutt model also collapses in the sense that inclusion of alternative variables, e.g. real government expenditure per capita, renders the agricultural output variable insignificant. Indeed, the significance of the government expenditure variable here confirms the possible importance of government expenditure for non-agricultural employment, the rural real wage and, therefore, rural poverty. And, indeed, including a government expenditure variable along with lagging the employment variable yields our preferred equation. Interestingly, this equation fitted to data up to 1987-88 accurately tracks the subsequent movement in rural poverty, including both the sharp upward movement in 1991 and 1992 and the reversal in 1993-94.20

Nonetheless, these observations on the basis of All-India data, though indicative, cannot be conclusive given that the degrees of freedom are few and because a number of possible explanatory variables are mutually correlated. For this reason, the excercise was repeated using state level data, in the form of a pooled time-seris and crosssection analysis with data up to 1992. In this exercise, poverty was regressed against agricultural output per rural person, state per capita SDP, a relative food price index calculated by dividing the index of the food price in the CPIAL by the SDP deflator, an inflation index based on the SDP deflator, and per capita real state development expenditure. All variables except the per capita SDP were significant, but, in addition, the inflation term was small and just crossed the significance level. The relative food price variable was easily the most statistically significant variable and it also was the most important in terms of its impact. The next important variable was state development expenditure, followed by agricultural output.

These results with pooled cross-section and time series data at the state level are in many ways similar to results obtained recently by Dutt and Ravallion (1995) with more or less the same data set, but restricted to the period up to 1989-90.21 In their model they regress poverty measures against agricultural output per hectare, state development expenditure and an inflation term, along with certain indicators of initial conditions (e.g., irrigation, infant mortality and female literacy). All the variables had the expected sign, and, interestingly, they find that state development expenditure was the most significant variable and that, unlike agricultural output which reduced poverty only by increasing mean consumption, state expenditure reduced poverty by increasing both mean income and improving income distribution. They did not include any relative price variable but our experiments with the same data suggest that this would have swamped the inflation term had they done so. Hence, the importance of state expenditure and of the relative food price appears to be fairly robust as factors explaining poverty both across time and space.

However, perhaps the most important result of this Dutt-Ravallion exercise is that it shows that, quite apart from the contemporaneous effect of prices, output and government spending, the extentio which a particular state could reduce poverty over time depended also on the *initial conditions* with respect to physical and human infrastructure, in terms of irrigation, female literacy and infant mortality, with which that state began. Thus, of the difference of 1.8 per cent per annum between the rates of poverty reduction in Kerala and Madhya Pradesh, fully 1.6 per cent per annum could

be attributed to the fact that Kerala began with higher female literacy (1 per cent) and lower infant mortality (0.6 per cent). Our own preliminary experiments with such *initial conditions* confirm the long-run importance for poverty reduction of health and education status, though much less so of irrigation, and suggest furthermore the importance of initial land distribution.

Clearly, this analysis suggests that both the benign agricultural output/inflation model and the relative price/state expenditure/rural non-agricultural employment models mentioned earlier are relevant for the determination of rural poverty. But the really important conclusion is that, of the two, the second is by far more important; agricultural output and inflation do matter, but as determinants of the incidence of poverty, the relative price of food and the level of government expenditure are even more important. In addition, the analysis points to an important and hitherto ignored longrun synergy between efforts at improving the health and education status of a society and its ability to bring down poverty over time.

#### V Policy Conclusions

The results above do not lead to any very optimistic prognosis about the effect of structural adjustment or of further 'marketist reform' on poverty. It is true that ceteris paribus an increase in agricultural output would reduce poverty and that, therefore, there is a case for diverting more resources to this sector. It is also true that any expansion of employment in the unorganised sectors, say through the rapid growth of labourintensive exports, would also reduce poverty And it remains extremely plausible that any policy which can moderate inflation without leading to a cut-back in employment opportunities would in general benefit the poor. Nonetheless, there are trade-offs involved in achieving each of this goals in the structural adjustment package, and it is precisely these trade-offs which are cause for pessimism.

The basic thrust of the structural adjustment strategy is to allow greater play to market forces and to ensure that domestic relative prices reflect the opportunities available in international trade. In theory, domestic liberalisation would cause a greater degree of commercialisation, and liberalisation of international trade would cause shifts in relative prices in favour of agriculture and exportables. Taken together, these are expected to bring about the desirable shift of resources towards agriculture and labour-intensive exports. However, the problem with this is that not only do these very mechanisms, commercialisation and a rise

in the relative price of agricultural products, act directly to increase poverty, but also that the magnitudes of the elasticity of poverty to these make it extremely unlikely that the direct loss on this account can be made up by the indirect benefits accruing from the better resource allocation that is expected to result thereby. For example, in almost every poverty equation reported above, the positive coefficient on the relative price variable is twice the absolute size of the negative coefficient on the agricultural output variable - implying that the elasticity of food production to the relative price of food would have to be greater than two if such a change in relative price is to reduce poverty through higher food production.

This cautions against any sudden opening up of the foodgrains sector to international trade, and, indeed, the caution here should be greater than simply one of managing a careful transition to world prices. The fact that the relative price specification is more important than the inflation specification suggests that the underlying problem is caused by more than a stickiness of money wages in the face of price increases. If such stickiness existed without any long-run impact of relative prices on poverty, the problem would have only been a transitional one which could be managed by keeping inflationary pressures in check either by a graduated movement to world prices or through a mofe effective stabilisation policy. However, since poverty is extremely sensitive to relative prices there is more than a transitory problem with opening up agriculture to international trade. Also, with government expenditure important for poverty, there is the further important trade off between this direct effect and the indirect effect, through inflationary pressures, of the fiscal policy stance. Given the relative importance of the government expenditure and inflation variables in the poverty equations, attempts to use contractionary expenditure policies to deal with inflation pressures, say as a result of a greater opening up to international trade, could prove to be a case of the medicine being worse than the desease.

In any case, there appears to be considerable evidence that the increased government spending during 1976-90 was among the principal reasons why India could record rather impressive declines in poverty during this period. However, it is also true that the sustainability of such expenditure increases in the future is more doubtful than ever before. During 1976-90, real per capita government, development, expenditure increased at an annual rate of 6 per cent per annum as against only a 3 per cent growth in per capita real GDP. Real government expenditure per capita fell 15 per cent during 1990-93, but increased again by 6 per cent

# Illustrious PAST

On July 20,1908, a lamp was lit in the city of Vadodara. It was the lamp of Bank of Baroda, which soon lit thousands of lamps in the banking arena. Both across the National and International frontiers. We have come a long way . from a capital base of Rs. 28 lakhs, deposits of Rs 1.9 lakhs, profits of Rs 2000 and a manpower strength of 20 to what we are today. Dedication to customer service and innovations were moving forces then are still so now

# Slorious PRESENT

A network of 2476 branches -38 of them in twelve countries spanning six continents. A 20 million plus customer-base. A dedicated work force of over 45,000 women and men. Business-base of over Rs. 44,000 crores. Deposits of over Rs. 28,000 crores and advances of over Rs. 16,000 crores. Business-per-employee of almost Rs 1 crore Gross profit of Rs 877 crores (highest among nationalised banks) and net profit of Rs 204 crores. Capital adequacy ratio of 11.2% (as against 8% stipulated) Better financials in terms of Return on Equity, Return on Assets and Gross Profits to Working Funds. And a will to excel on the National and International frontiers.

# Golden FUTURE

Our sights are set high. Vision 2000, for which strategic plans have been drawn up, envisages an increase in the customer-base from the present 20 million to 50 million by 2000 AD and 100 million by 2005 AD. Our plan is to record a business level of Rs. 86,000 crores and a profit level of Rs 1000 crores by the turn of the century. We are technologically upgrading ourselves to transform the Bank into a highly competitive, market-oriented, technology-driven bank dedicated to better customer satisfaction and socio-economic development in the country. And achieve excellence in International banking with commitment and innovations. Our goal Make every branch of the Bank a

meeting place of banking pleasure for every customer.

in 1993-94. The earlier expansion of government expenditure had led to large fiscal imbalances despite the fact that tax-GDP ratios had then grown quite significantly. On the other hand, both GDP growth rates have been lower and tax-GDP ratios have been falling in the post-reform period. It is therefore unlikely that the pace of growth of government expenditure can be sustained unless GDP grows at least 8 per cent per annum or there is a definite policy of increasing the tax-GDP ratio significantly.

Given this fiscal reality, and the fact that non-agricultural GDP does not appear to have much impact on poverty except through its effect on the sustainability of government expenditure, it is obvious that there will be problems with maintaining the pace of poverty reduction. Even if GDP growth increased, the current fiscal priorities make it unlikely that this would be reflected fully in public expenditure. One possibility discussed in this context is to alter the composition of government expenditure so that it is more directly focused on poverty alleviation. But, although this is possible and desirable, a note of caution must be sounded on this at the outset. In our regression excercises, we played around with different components of government expenditure, and the results suggested, somewhat surprisingly, that it was the broader measures of such expenditure which had a greater poverty alleviation effect, at least when poverty is measured by the head count ratio, than narrower and more focused measures such as that on agriculture and rural development.22

There are two possible reasons for this First, it may well be the case that the existing poverty alleviation programmes are not particularly effective and that their impact on poverty is no greater than other government expenditure. If so, there is room for improvement in the design of expenditure focused towards poverty alleviation. And, indeed, a case can also be made out that it may be possible to transfer funds from such programmes to rural capital formation without endangering the poverty alleviation impact. But, secondly, it also appears that what is really at issue are much broader multiplier effects of overall government expenditure. Clearly much more work is required in this area to identify wavs in which the impact of a given amount of expenditure can lead to more poverty alleviation, but, although there are certainly likely to be ways of achieving this, it should not be expected that it will be possible to cut-back overall government expenditure without any adverse effect on poverty. The real significance of government expenditure appears to be that it is this which imparts any 'trickle-down' characteristic to the growth process, something which appears quite weak if only GDP growth is considered.

Nonetheless, since this effect is likely to be greater if government expenditure is properly targeted, it is necessary to attempt a brief evaluation of the contribution of government anti-poverty schemes in the reduction of poverty. There have been numerous evaluations of these made by the government and by independent researchers, and no attempt will be made here to review this literature which attempts to measure the effectiveness with which particular schemes have been able to target the poor. Suffice it is to note that such evaluations have by and large found that asset-creation schemes. such as the Integrated Rural Development Scheme, have had less success in alleviating immediate poverty than rural employment programmes, although even the latter have leakages and are often criticised for being a palliative whose effectiveness at permanent poverty reduction are rather low. However, comparing the official figures on employment schemes with independent data from the NSS, four points are worth making. First, with the NSS reporting a quantum of employment in public works which matches official data well, fears about large leakages may be rather exaggerated. Secondly, the schemes appear to be reasonably welltargeted in that they are availed of most by casual labour households which have both the highest poverty and the highest personday unemployment, but the regional distribution of employment through such programmes appears to be concentrated in a few western Indian states, and also public works appear to have been much more effective in 1987-88, a drought year, than in more normal years. Thirdly, it seems unlikely that the effective transfer through such schemes was much lower than the wage cost as a result of incomes foregone by the workers to take up such employment.23 Fourthly, possibly because they are well targeted, public works appear to have been more effective in moderating the severity of poverty rather than its head count incidence 24

Conceptually, if viewed primarily as an anti-poverty measure, a well targeted public works programmes should not provide incentives for the non-poor to participate and nor should there be impediments to participation by anyone who is poor. At least till 1987-88, Indian schemes seem broadly to have passed the first test but, except possibly in Maharashtra, failed the second both because of a paucity of funds and a lack of official commitment, except at times of natural disasters. Since then, confusion about the intention behind such schemes seem to have increased. First, wages offered have been increased to the statutory minimum wage rate which is often higher than locally prevailing wages, thus making participation more attractive. Second, despite this, funds available for such schemes have been cut in real terms, causing job availability to be even more rationed. Finally, as a result of a misplaced importance given to the head count poverty incidence measure there is a feeling that these schemes have failed to reduce poverty, and this, combined with a general presumption that investment rather than doles are what is really necessary, have led many to argue for an increase in the materials and expertise content of these schemes, at the cost of their unskilled labour content, so as to make them more viable instruments of rural investment.

These reactions are confused because the primary goal of an anti-poverty measure is not the creation of assets and not is its purpose a general redistribution of income, say by increasing the general wage level. This is not to argue that these are not laudable objectives but simply to point out that attempts to chase too many objectives without substantially increasing the budget available risks diluting the primary goal of poverty alleviation. Both higher wage rates and a lower component for unskilled labour in these schemes reduce their transfer content And, these objectives, by attracting richer workers and/or by directing employment to regions where viable investment projects. rather than the poor, exist are also likely to make for much less effective targeting. Possibly, the correct approach would be to make employment guarantee the primary concern of such programmes, setting the wages paid to levels where the demand for such employment would broadly match the funds available. Clearly, if more funds can be directed into such programmes the wage rate paid can be increased, and with sufficient expenditure even the general wage rate influenced within the employment guarantee framework. The employment guarantee aspect should, however, be the primary concern and higher wages the secondary concern because only this priority would keep out the relatively rich while allowing the poor unimpeded access.

Secondly, the best way to dovetail productive investment into such a programme would possibly be to give a wage subsidy equal to the employment guarantee wage rate for each unskilled worker working on a class of well-defined approved investment projects, delinking project choice from the agency implementing the guarantee scheme and treating the rest of the project cost and benefit on par with any other. With the employment guarantee scheme in place, this need not cost the exchequer any more and yet the linkage between poverty alleviation and productive investment through labourintensive schemes could be decentralised Needless to say, this means that other project costs would have to be met from outside the

employment guarantee budget. But this is the proper way of proceeding because while there is a case for subsidising employment if there is paid underemployment at the normatively chosen employment guarantee wage rate, there is no case to subsidise any particular investment more simply because it is selected by the agency implementing the employment guarantee scheme.

However, the main lesson from earlier sections is that the basic thrust towards permanent reduction of poverty must take the form either of increasing employment in agriculture, mainly through better irrigation and multiple cropping, or of increasing the stock of viable selfemployment opportunities or regular jobs in non-agriculture. It is towards these objectives that rural investment should be encouraged while employment guarantee provides the framework within which this can be done without sacrificing the need to combat poverty immediately. Yet, because the reforms themselves have aspects which tend to increase poverty, and because fiscal considerations mean that it might be difficult to increase both agricultural investment and the expenditure on anti-poverty schemes, there will be difficulties in the future.

Under these circumstances, it is clear that if poverty reduction is to be a serious part of the agenda in the reform period, the reforms themselves should have an explicitly redistributive content. This would require cuts in subsidies to the rich and also higher taxes to maintain and increase the expenditure relevant for the poor. In addition, the old issues of land distribution and the provision of universal primary health and education must again be put back on the agenda. But, more than anything else, it must be recognised that a 'reform' strategy which aims to withdraw the state from investment, liberalise finance and thus divert finances from the state to the private sector, liberalise agricultural trade and thus enrich the rich at the direct cost of the poor, and seeks to control inflation and BOP problems through deflation and devaluation is at its root a fundamentally inequitous adventure.

#### Notes

[This is a slightly revised version of a paper delivered at the Workshop on Economic Reforms and Poverty Reduction organised jointly by the Institute of Development Studies, Sussex and the Lal Bahadur Shastri National Academy of Administration, Mussoorie, and held in Mussoorie in February 1996.]

- Jayati Ghosh, 'Trends in Rural Employment and the Poverty-Employment Linkage', ILO-ARTEP, New Delhi, 1993.
- 'Rural Development', including special area programmes, makes its appearance as a separate plan head only in the Sixth Plan (1980-85). The actual expenditure under this head was 7.8 per cent of total plan expenditure. of the central and state governments taken together, during the Sixth Plan rising to 8.6 per cent in the Seventh Plan (1985-90). The share of Plan expenditure under the different head 'Agriculture and Allied Sectors', dropped from 12.3 per cent in the Fifth Plan (1974-79) to 6.1 per cent in the Sixth Plan to 5.8 per cent in the Seventh Plan. Plan expenditure on 'Irrigation and Flood Control' also fell as share of total plan outlay from 9.8 per cent in the Fifth Plan to 10 per cent in the Sixth Plan to 7.6 per cent in the Seventh Plan. Thus, the total of these heads maintained a roughly constant share of total Plan expenditure, but there was a shift from specifically agricultural to wider concerns. In addition to these a considerable amount of government expenditure under other heads, notably Social services, occurs in rural areas. The rural share of these is likely to have increased.
- All these figures are on the basis of the NSS usual status activity concept. However, very similar results are obtained on the basis of the NSS weekly status concept also. Unfortunately, figures are not available by the more sensitive daily status concept for the NSS 'thin' samples between 1989-90 and 1992 The range of values indicated above are necessitated by the fact that NSS population estimates vary somewhat from the figures issued by the Registrar-General. The absolute fall in non-agricultural employment is greater if the unadjusted NSS figures are used, the lower estimates assume the NSS ratio of workers to population but the Regist.ar-General's population estimate Sometimes doubts are expressed about the validity of employment estimates from the NSS 'thin' samples, but see Bhalla, S 'Workforce Restructuring, Wages and Want Recent Events, Interpretations and Analysis', Presidential Address at the 37th Annual Conference of the Indian Society of Labour Economics, printed in The Indian Journal of Labour Economics, January-March 1996.
- Tendulkar, S D and L R Jain, 'Economic Reforms and Poverty', Economic and Political Weekly, June 10, 1995.
- For the methodology recommended, see Planning Commission, GOI, Report of the Expert Group on Estimation of Proportion and Number of Poor, July 1993. For details of actual calculations, see Chandrasekhar, C P and Abhijit Sen, 'Has Poverty Declined with Reforms?', Macroscan, Businessime, January 23, 1996.
- An important point which needs discussion relates to the use of thin sample data. It is sometimes suggested that these data should not be used because of their small sample size, especially at the state level. However, since what matters really is the effect of small samples on the variance of the estimates, these variances were calculated and confidence tests were done. The results of

- these confidence tests show that, comparing 1989-90 with 1992, poverty increased significantly in all states except Kerala and Karnataka. Comparing 1989-90 with 1993-94, poverty increased significantly in Assam, Bihar, Gujarat, Haryana, Maharashtra. Punjab and Uttar Pradesh, it declined significantly in Andhra Pradesh, Karnataka, Kerala and Tamil Nadu; and the changes were statistically insignificant in the remaining states.
- It is interesting to observe that the share of private investment in GDP has fallen in the post-reform period. But this conceals a major asymmetry between investments in the corporate and the household (i.e., small scale) sectors: gross fixed capital formation of the household sector declined from 9.5 per cent of GDP in 1990-91 to 5.3 per cent in 1993-94, while corporate investment increased from 3.8 per cent of GDP to 7.2 per cent. Similarly there is an asymmetry in the growth rates of corporate and non-corporate entities in the manufactured sector. Compared to a decadal average of 8.2 per cent per annum during the 1980s, and 8.9 per cent in 1990-91, the index of manufacturing output tell by 0.8 per cent in 1991-92, and grew only 2.2 per cent in 1992-93 and 5.6 per cent in 1993-94, before returning to a pre-reform growth rate of 8.7 per cent in 1994-95 Significantly, however, the large-scale private corporate sector performed better than the economy. This sector weathered the crisis year 1991-92 rather well, managing a sales growth of 9 per cent in real terms, the same as the 1980s average Real sales growth slowed down to 2 per cent in 1992-93 because of public expenditure cuts. but rebounded to 8 per cent in 1993-94 and soared to 16 per cent in 1994-95 as spending cuts were restored Moreover, the share of gross profit in corporate sales has risen continuously, from 14 per cent in 1990-91 to over 16 per cent in 1994-95, and, because of cuts in corporate taxation, profits after tax have risen even more. Thus, the adverse effects of stabilisation and structural adjustment policies on investment appear to have been concentrated on smaller enterprises. This is in part an outcome of the fact that changes in the financial sector, which boosted equity markets and made credit more costly and scarce, have tended to divert finance to larger enterprises. But, in part, this was also a reflection of changing demand patterns
- 12 Unlike previous devaluations which were accompanied by the imposition of export duties on agricultural products to dampen primary price increases, the devaluation in 1991 was accompanied by an withdrawal of subsidies on manufactured exports and the announcement that there would not be any further discrimination against primary goods exports.

- Composition of Economic Growth", World Bank Economic Review, 1996.
- 16 See, for example, Nayyar, D and A Sen, 'International Trade and the Agricultural Sector in India' in G S Bhalla (ed), Economic Liberalisation and Indian Agriculture, ISID, 1994.
- 17 Ravallion and Dutt op cit Background Paper to the 1995 World Development Report, WPS 1405, World Bank.
- 18 When this model estimated up to 1987-88 is extrapolated it yields expected poverty ratios of 33 1 and 34.5 per cent in 1992 and 1993-94 respectively as against actuals of 43.5 and 38 7 per cent for those years. It must be noted that these models were fitted to the Ravallion-Dutt data. Their poverty estimates for 1989-90 and 1992 are 34 3 per cent and 43.5 per cent respectively. In contrast, the corresponding Tendulkar-Jain estimates are 37.9 and 48.1 per cent, implying an even larger increase in poverty in the immediate post-reform period than the Ravallion-Dutt estimate.
- 19 The predicted value for 1992 turns out to 43 per cent as against the actual of 43.5.
- 20 The predicted values are 43.7 per cent and 40.4 per cent in 1992 and 1993-94, as against actuals of 43.5 per cent and 38.7 per cent respectively.
- 21 Dutt, Gaurav and Martin Ravallion 'Why Have Some Indian States Done Better than Others at Reducing Rural Poverty?', mimeo, Policy Research Department, World Bank, September 1995
- We included many alternative measures of government expenditure, such as expenditure on agriculture, rural development and social. sectors, in both the all-India and state level equations. In almost every case these more focused public expenditure variables performed worse than the more general public "development" expenditure, which includes almost all public expenditure other than interest payments and administration However, this analysis, which must be carried out at the state level to give sufficient degrees of freedom, is continuing. It is possible that better specification will lead to more definite results. One result already available is that rural employment schemes appear to have a significant poverty alleviation effect if the squared poverty gap measure is used, although not with the head count measure
- This is a theoretical possibility often raised when comparing such schemes with jure transfers (see e g, Gangopadhyay, S and Subramanian S, 'Optimal Budgetary Intervention in Poverty Alleviation Schemes' in S Subramanian (ed), Themes in Development Economics, OUP, Delhi, 1992) However, our regressions suggest a positive relationship across states, holding agricultural output constant, between employment in public works and employment excluding public works. For a more sophisticated micro-level excercise which also concludes that incomes foregone were small, see Ravallion, M and G Dutt, 'Is Targeting through a Work Requirement Efficient? Some Evidence from Rural India', mimeo, World Bank 1993

# India's Checkered History in Fight Against Poverty

#### **Are There Lessons for the Future?**

#### Martin Ravallion Gauray Datt

Looking back 40 years or so, progress against poverty in India has been highly uneven over time and space. It took 20 years for the national poverty rate to fall below – and stay below – its value in the early 1950s. And trend rates of poverty reduction have differed appreciably between states. This paper provides an overview of results from a research project which has been trying to understand what influence economywide and sectoral factors have played in the evolution of poverty measures for India since the 1950s. There are some clear lessons for the future.

THERE has been much debate about how best to fight absolute poverty. Total numbers of poor people in the world – by almost any accepted standard – are continuing to rise. The urgency of resolving the debate, and taking effective action, is greater than ever.

The extent to which poor people share in economic growth has been one of the most contested issues. Some observers have argued that "distribution must get worse before it gets better" in developing countries, and that this puts a severe brake on the prospects for pro-poor economic growth. There have also been debates about the effects of growth in specific sectors. For example, some have argued that the benefits of the 'green revolution' (which resulted in substantial gains in agricultural yields through new seed varieties and irrigation) were captured by relatively well-off farmers, and brought little or no gain to the rural poor. Others have pointed to farm-output growth as the key to poverty reduction, both directly and via its effects on rural wage rates.

There would be little risk of exaggeration in saying that the position one takes in such debates has great bearing on long-standing issues of development strategy and policy reform. The link between growth and poverty, and the interaction with other factors (including human resource development), has also taken on new urgency in the wake of recent macroeconomic difficulties and adjustment efforts in many developing countries.<sup>3</sup>

However, these are difficult issues to resolve empirically, not least because of the I paucity of representative and reliable data over time on the living standards of poor people. Amongst developing countries, India has relatively good data for addressing these issues. At the time of writing, one could compile a time series of consumption data from 34 National Sample Surveys spanning 1951-92. This is one of the longest series of national household surveys suitable for tracking living conditions of the poor. Most of the surveys are large enough to be considered representative at the urban and rural levels for most states, and they appear to be reasonably comparable over time since the

basic survey method has changed relatively little. Other data (on price indices and explanatory variables) are also available on a reasonably consistent basis. Although there are data problems (some of which we can make corrections for), they are modest by the standards of cross-country comparative studies. The existence of a time series of consumption distributions spanning 40 years represents a unique opportunity to study the link between living conditions of the poor and the key macro-economic and sectoral variables which are thought to have important influences on progress in reducing poverty.

We have used these data to study the past evolution of living standards in India. We have asked: How have comparable measures of poverty in India evolved since the 1950s? Has the experience been different between urban and rural areas and between different states? How have measures of poverty responded to changes in economy-wide and sectoral variables? What has been the relative importance of economic growth versus changes in distribution? What role has been played by the sectoral composition of economic growth? How important have changing wages and prices been? Why have some states of India done so much better than others in the fight against poverty? What role have differences in the initial levels of human development played, versus other factors such as physical infrastructure endowments? This paper provides an overview of the results of this research. We avoid details on data and methods, which are described more fully in a series of papers from the project.4

#### DATA ON POOR PEOPLE

To address the questions posed above, we constructed a new set of consistent estimates of various poverty measures for India over the period 1951 to 1992 from the National Sample Sur 'ey (NSS) data. We aimed to measure 'absolute poverty', by which we mean that the extent of any household's poverty depends solely on its own absolute standard of living (for example, a household does not switch from being poor to non-poor

when it moves across sectors unless its standard of living has changed). Following now well-established and defensible practice for India and elsewhere, the standard of living was measured by consumption expenditure (including imputed values for consumption from own production). We only studied 'poverty' in the narrow (though unquestionably important) sense of "command over commodities"; we do not deny that there are aspects of a broader concept of 'well-being' which are not captured by our poverty measures."

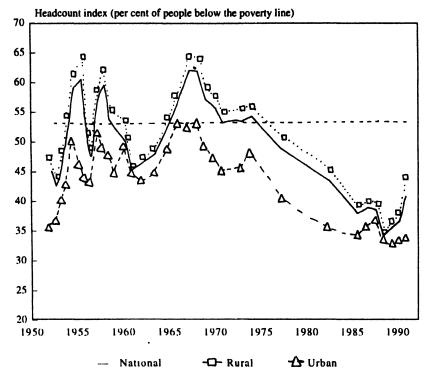

The poverty lines used were those defined by India's planning commission.' The rural poverty line is Rs 49 per month and the urban line is Rs 57 per month at October 1973-June 1974 all-fidia rural and urban prices respectively. The nominal consumption distributions for each survey data were then converted to constant prices using consumer price indices for urban and rural areas which were anchored to the consumption patterns of low-income workers.

Three different poverty measures were used (1) The headcount index, given by the percentage of the population who live in households with a consumption per capita less than the poverty line. This measures the incidence of poverty; (ii) The poverty gap index, defined by the mean distance below the poverty line expressed as a proportion of that line (where the mean is formed over the entire population, counting the non-poor as having zero poverty gap). This reflects the depth of poverty, as well as its incidence; (iii) The squared poverty gap index, defined as the mean of the squared proportionate poverty gaps. Unlike the poverty gap index, this measure reflects the severity of poverty, in that it will be sensitive to inequality amongst the poor.11-12 The estimated poverty measures were then collated with a variety of macro-economic and sectoral variables.13

How Much Progress Has India Made in Fighting Poverty Since the 1950s?

Table 1 gives our estimates of the three poverty measures for eight periods formed by aggregating NSS rounds, Figure 1 gives

FIGURE 1: POVERTY IN INDIA 1951-92

the estimates of the headcount index for each survey round. (The pattern of change was very similar for the other two poverty measures) Several points emerge:

The period from the early 1950s up to the mid-1970s was characterised by fluctuations in poverty without a real trend in either direction. The average headcount index was 53 per cent in 1951-55 (marked in Figure 1), about the same as its average value in 1970-74. After that there was a significant decline in poverty incidence (and the depth and severity of poverty fell too), though this was not a continuous decline. It thus took over 20 years for the poverty measures to finally fall below – and stay below – their values in the early 1950s.

Changes in rural poverty closely follow those at the national level, which is not surprising given that a large proportion of India's population lives in rural areas (about 74 per cent even at the end of the period). It is more notable that a similar pattern over time also holds for urban poverty (Figure 1). Common causative factors appear to be at work.

The reduction in poverty since the early 1970s has been sizeable; between 1969-70 and 1992, the national headcount index declined from 56 to 41 per cent. Yet India's progress against poverty has been modest when compared to the standards set by some countries in east Asia. For example, Indonesia's headcount index was 58 per cent in 1970—very close to our estimate for India at that time. But by 1993 (keeping the same real poverty line over time), we estimate that

the headcount index for Indonesia had fallen to 8 per cent, about one fifth of India's headcount index in 1992.<sup>17</sup>

HOW IMPORTANT TO INDIA'S POOR WAS ECONOMIC GROWTH AND CONTRACTION?

We look first at the effect of aggregate economic growth and contraction on poverty. Comparing successive survey

rounds, we regressed the percentage change in each of the three poverty measures on various measures of the rate of aggregate economic growth between the same rounds. Based on the regression coefficients, Table 2 gives our estimates of the percentage change in each poverty measure to be expected from a 10 per cent growth rate for (i) the mean consumption per person as estimated from the NSS; (ii) mean consumption per person estimated from the national accounts and population census; and (iii) mean net domestic product per person, also from the national accounts and census.<sup>18</sup>

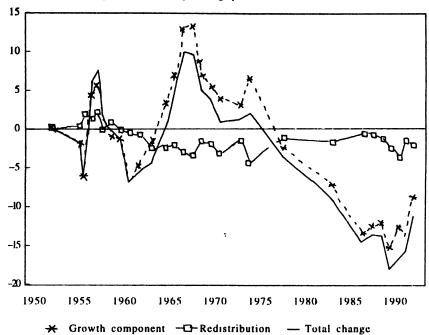

The national poverty measures responded significantly to all three measures of economic growth. For example, a 10 per cent increase in mean consumption resulted in a 12-13 per cent drop in the proportion of people who are poor, representing a 10-11 per cent drop in the number of poor, at India's rate of population growth. The responses are higher if one uses the NSS estimate of mean consumption, rather than the national accounts estimate, though the difference is small for a given poverty measure. The responses are lowest for net domestic product. This may be due to intertemporal consumption smoothing which may make poverty (in terms of consumption) less responsive in the short-term to income growth than to consumption growth.

Notice too that the responses tend to be greater if one uses the poverty gap index rather than the headcount index, and the response is largest for the squared poverty gap, which is sensitive to both the depth and

TABLE 1. POVERTY IN INDIA 1951-1992

| NSS Rounds         | Period    | Rurai | Urban | National |
|--------------------|-----------|-------|-------|----------|
| Headcount index    |           |       |       |          |
| 3.8                | 1951-55   | 54.77 | 42 70 | 52.66    |
| 9-15               | 1956-60   | 53.96 | 47 06 | 52.74    |
| 16-19              | 1961-65   | 48.59 | 45.46 | 48 02    |
| 20-24              | 1966-70   | 60.44 | 50.90 | 58.60    |
| 25, 27, 28         | 1971 - 75 | 55.27 | 46.04 | 53.39    |

Cumulative change since 1951-52 (percentage points)

severity of poverty. This means that the impacts of growth and contraction in India were not confined to those near the poverty line, but reached deeper.

Redistribution played a role in the long run changes in poverty in India. Any change in a poverty measure can be decomposed into a growth component and a redistribution component. PRoughly speaking, the growth component is the change in the poverty measure which would have occurred if inequalities had not changed, while the redistribution component is the change in the poverty measure that one would have found if there had been no change in the mean. By adding each component over time we can assess the cumulative total impact of growth or redistribution. Figure 2 gives the results.<sup>20</sup>

It can be seen that the redistribution component did help over the whole period. Thus, for India, our results reject the old view (still held in some quarters) that distribution must get worse as a low-income country grows. Nonetheless, the overall contribution of redistribution to change in the headcount index has not been large in the long run. The growth in mean consumption has been more important, accounting for about 80 per cent of the cumulative decline by the end of the period.

Redistribution mattered more to the other two poverty measures. For the poverty gap index, the redistribution component accounted for about 40 per cent of the cumulative decline by the end of the period; its contribution was 47 per cent for the squared poverty gap index. Favourable redistribution has thus been quite important for changes in the depth and severity of poverty.

Most of the pro-poor impact of redistribution was realised early on, during the early to mid-1960s, well before the onset of the sustained decline in the national poverty measures. Since the mid-1960s, the redistribution component fluctuated without making a further addition to its total longrun impact on national poverty. (This holds for all three poverty measures.) The gains to the poor since about 1970 have been almost entirely due to growth.

The latter finding might be taken to imply that public efforts at pro-poor redistribution in the 1970s and 1980s failed. However, one should be wary of drawing that conclusion since we do not know the counter-factual of what would have happened without those efforts. Possibly distribution would have got worse.

Turning next to the sectoral composition of growth, we found that the changes in national poverty have been for the most part driven by changes in rural poverty. Figure 3 gives the cumulative (population-share weighted) contributions of both the urban and rural sectors to the national headcount index. The rural sector accounted for more than three-quarters of the total decline in national poverty measures over the whole period.21 Nonetheless - despite the substantial sectoral shifts in national output that have occurred over the last 40 years or so poverty in India is still overwhelmingly rural. In 1992, three-quarters of India's poor lived in rural areas.

We also looked closely at the interlinkage between the sectoral composition of economic growth and the urban-rural composition of poverty, using econometric methods to disentangle the various effects within and across sectors.22 The main conclusion was that the relative effects of growth within each sector, and its spillovereffects to the other sector, reinforced the importance of rural economic growth to national poverty reduction in India. Both the urban and rural poor gained from growth within the rural sector. By contrast, while urban growth reduced urban poverty, it also had adverse distribution effects within urban areas which militated against potentially higher gains to the urban poor. And urban growth had no discernible impact on rural poverty. The process of growth through rural-to-urban migration contributed very little to poverty reduction in India.

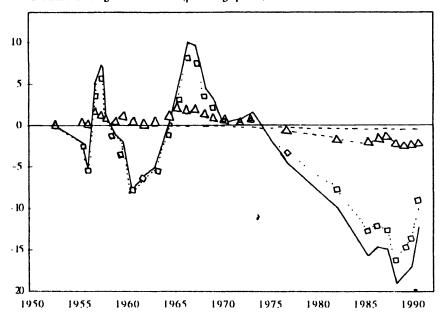

When the growth in national income was broken down by output-based sectors, we found that there were marked sectoral differences in the poverty impacts. Both primary (mainly agriculture) and tertiary (trade, services, transportetal) sector growth reduced poverty nationally, and they also did so within both urban and rural areas. By contrast, secondary (mainly manufacturing) sector growth brought no discernible gains to the poor in either sector. In the historical shift from primary to secondary and tertiary sectors it was the latter sector which delivered the bulk of the gains to India's poor.

TABLE 2: How RESPONSIVE WERF NATIONAL POVERTY MEASURES TO ECONOMIC GROWTH IN INDIA?

FIGURE 3: URBAN-RURAL COMPOSITION OF CHANGE IN THE HEADCOUNT INDEX (Cumulative Changes in the Urban and Rural Components and Population Shift Effects)

Cumulative change since 1951-52 (percentage points)

-D- Rural component -- Urban component -- Population shift -- Total change

The relative lack of an impact of secondary sector growth on poverty reflects the type of development strategy India pursued since the second plan in the late 1950s, which emphasised capital-intensive industrialisation within a largely closed-economy regime. It is not surprising that such industrialisation brought negligible direct gains to the nation's poor, who depend heavily on the demand for relatively unskilled labour.<sup>24</sup>

## DID THE RURAL POOR BENEFIT FROM AGRICULTURAL GROWTH?

Since rural poverty has been so important, we turned our attention to this sector. Here we examined how much India's rural poor benefited from agricultural growth, what role the labour market played, whether the impacts were distributionally biased one way or another, and how important macroeconomic stability was to the rural poor.

We collated the household survey data with data on agricultural wages, prices and output, and estimated a dynamic econometric model jointly determining rural poverty measures and real wages.<sup>24</sup> The model had a triangular structure in which the rural poverty measure was hypothesised to be a function of both the real agricultural wage rate and the average farm yield per unit area (as well as other variables), and the real wage rate was also a function of the farm yield and other variables.

The results indicated that all three poverty measures responded significantly in the short run to changes in agricultural wages as well as to average farm yields. And wages also responded significantly to farm yields, presumably through effects on labour demand, such as due to multiple cropping. Higher yields thus helped reduce absolute poverty through induced wage effects, as well as the more direct channels, including effects on both employment and own-tarm productivity.

Neither the poverty measures nor real wage rates adjusted instantaneously to changes in farm yields. The combined effect of this stickiness in both variables was that the short-run gains to poor people of agricultural productivity growth were far lower thar the long-run impacts. Also, the short-run effects on rural poverty operating via the real wage rate were minor compared to the direct effects of higher own-farm yields. But in the long run, the wage effects did matter, accounting for about one-third of the long run response of absolute poverty (for all three measures) to a yield increase. The process through which India's rural poor participated in the gains from agricultural growth did take time, though about half of the long-run impact occurred within three years of an initial gain in farm yield.

#### DID INFLATION MATTER?

We found evidence of an adverse shortrun impact of inflation on real agricultural wages and (hence) absolute poverty in rural areas. The effect of inflation was to reduce real wages in the short term, because nominal agricultural wages responded sluggishly to inflation. Nominal wages catch up eventually. But we found that the adverse short-term impact on the rural poor was sizeable. For example, we estimate that a once-and-for-all 20 per cent increase in the price level would result in a drop of 13 per cent in the current year's real wage rate in agriculture, and an increase of 5 per cent in the rural headcount index. The impacts on the other poverty measures would be even higher; the squared poverty gap would rise by 9 per cent.

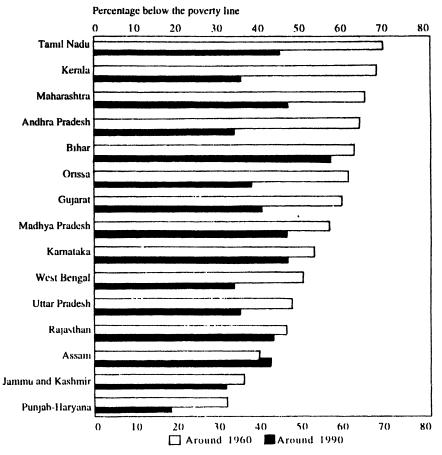

## DID SOME STATES PERFORM BETTER THAN OTHERS IN REDUCING RURAL POVERTY?

The regional disparities in levels of living in India have been large. For instance, the proportion of the rural population of the state of Bihar living in poverty in 1990-91 was about 58 per cent, more than three times higher than the proportion (18 per cent) in the (combined) states of Punjab and Haryana. Some of these differences appear to have persisted historically, though there were also differential trends across regions. Looking back over time, the more striking - though often ignored - feature of the Indian experience has been the markedly different rates of progress between states; indeed the ranking of states around 1990 looks quite different to that 30 years earlier, as can be seen in Figure 4 which compares headcount indices around 1960 with those around 1990 (The picture looks very similar for the other two poverty measures.25) For example, the southern state of Kerala moved from having the second highest rural poverty rate around 1960 to having the fifth lowest around 1990."

Regressing the log of each poverty measure against time, there was a trend decrease (significant at the 5 per cent level or better) in all three measures in 9 of the 15 states, viz, Andhra Pradesh, Gujarat, Kerala, Maharashtra, Orissa, Punjab and Haryana, Tamil Nadu, Uttar Pradesh and West Bengal. The trend was not significantly different from zero at the 5 per cent level in the other six states of Assam, Bihar, Jammu and Kashmir, Karnataka, Madhya Pradesh, and Rajasthan; there was not a significant positive trend for any state for any poverty measure. There is a tendency for the absolute size of the trend to be higher for the poverty gap than the headcount index, and it was highest for the squared poverty gap.

In terms of progress in both raising average household consumption and reducing rural poverty, the state of Kerala turns out to be the best performer over this period. The second, third and fourth highest trend rates of consumption growth were Andhra Pradesh, Tamil Nadu, and Maharashtra respectively. In terms of the rates of poverty reduction, the second, third and fourth states were Andhra Pradesh, Punjab and Haryana, and Gujarat; the ranking is invariant to the

Averages for first three survey rounds and last three

choice of poverty measure though differences in their rates of poverty reduction are not large. The worst performer was Assam by all measures. The other poor performers were Bihar, Jammu and Kashinir, Karnataka, Madhya Pradesh and Rajasthan; the exact ranking varies by the measure used.

The states which had the highest trend rates of growth in mean consumption tended to have the highest trend rates of poverty reduction, and the correlation is very strong (the correlation co-efficient between the trend rate of reduction in the headcount index and the trend rate of consumption growth is 0.85, the correlation is about the same for the other two poverty measures). Both these variables may well have been influenced by similar factors. Next we look at what those factors might be.

WHAT ACCOUNTS FOR THE DIFFERING RAILS OF PROGRESS IN REDUCING POVERTY?

Every state has its own story with a mixture of both successes and failures at public action against poverty in different periods. <sup>27</sup> There were differences between states in the impacts of (ostensibly similar) interventions, as well as differences between states in the package of interventions pursued; and in both respects experiences in a given state changed over

time. We cannot hope to capture all this variance in experience – for one thing we would quickly run out of degrees of freedom. Here our aim is solely to look for any empirical regularities that can account for at least a reasonable share of that variance.

The inter-state differences in progress at fighting poverty allowed the project to study the impact on the trend rate of poverty reduction of a range of variables, including regional differences in human and physical resource development. A pooled model was estimated, giving 310 observations (15 states over 21 NSS rounds, though with some missing observations, or inadequate sample sizes). A model was estimated for each poverty measure, with both time varying and static explanatory variables. The key explanatory variables were current and lagged real agricultural output per hectare. current plus lagged real non-agricultural output per capita, the rate of inflation, lagged real state development spending per capita, and the state's initial (around 1960) irrigation rate, infant mortality rate, and female literacy rate; the latter three variables were allowed to influence the rate of change in the poverty measures (thus entering the model interacted with time).38 The estimated models could account for about 90 per cent of the variance over time and across states in the poverty measures.<sup>29</sup>

The results indicate that higher growth rates in agricultural yields and real non-agricultural output per capita, lower rates of inflation and higher growth in state development expenditure all led to higher rates of progress in both raising average consumption and reducing all three measures of absolute poverty.

The results also suggest that inter-state differences in initial conditions of human and physical resource development played an important role; higher initial irrigation intensity, higher literacy rates and lower initial infant mortality rates all contributed to higher rates of consumption growth and poverty reduction. Initial inequalities in access to physical and human infrastructure appear to have been an important factor in longer-term rates of poverty reduction. 40 Consider Bihar, one of the worst performers in poverty reduction (Figure 4). The poor in Bihar suffered from the state's slow growth in agricultural yields. But the state's poor initial conditions were also an important factor. The incidence of poverty in Bihar declined at a trend rate of only 0.1 per cent per year. We estimate that this would have risen to 1.2 per cent if Bihar had started off with Kerala's level of human resource development in the 1960s.

By and large, the same variables determining growth in average consumption mattered to rates of progress in reducing poverty. Most of the effects on absolute poverty were transmitted through growth in average consumption rather than redistribution, though none of the factors which reduced absolute poverty had adverse effects on distribution. Thus, there was no sign of a trade-off between growth and propoor distributional outcomes.

#### LESSONS FOR THE PUTURE

Our investigation suggests that economywide variables do matter to India's poor, they have generally gained from economic growth, and lost from contraction, they have also been furt by inflation. The net gains to the poor since the early 1970s can be attributed in large part to economic growth—distribution changed little from the point of view of the poor, though it appears to have been more important in the 1950s and 1960s, when there was rather less growth

The experience of the past 40 years offers support for the view that a stable macropolicy environment, combined with micropolicy reforms conducive to economic growth, can help greatly in reducing absolute poverty in India. However, our results also reveal important nuances concerning the pattern of growth, and the importance of other contingent factors, including human and physical infrastructure.

Our results point clearly to the quantitative importance of the sectoral composition of economic growth to poverty reduction in India. Fostering the conditions for growth in the rural economy – both primary and tertiary sectors – must be considered central to an effective strategy for poverty reduction in India. At the same time, the relative failure of India's past industrialisation strategy from the perspective of the poor points to the importance of successful transition to a strategy capable of absorbing more labour, particularly from rural areas.

But our results also point to the longerterm importance of investing in human and physical infrastructure as a complement to pro-growth reforms in India. Controlling for growth in farm and non-farm sectors, we find significant effects on trends in absolute poverty reduction of the differences between states in initial conditions related to infrastructure.

A final lesson concerns the importance of being able to credibly assess an economy's performance in reducing poverty. Though less than ideal in some respects, the data base available for poverty analysis in India is good by international standards. Many other countries have had far fewer objective socioeconomic surveys on which poverty monitoring can be based, or their surveys have been severely wanting in terms of coverage (lacking, for example, a sound consumption module) or comparability over time. The very fact that for India we can obtain the data needed to address the questions posed above carries an important message for other countries today, and India in the future.

#### Notes

[For their comments we are grateful to Jyotsna Jalan, Peter Lanjouw, Dominique van de Walle, Quentin Wodon, and the *EPW*'s referee. This paper summarises results of a research project, 'Poverty in India, 1951-92', supported by the World Bank's Research Committee, under RPO 677-82. However, these are the views of the authors, and should not be attributed to the World Bank, or any affiliated organisation.]

- 1 See Ravallion and Chen (1996) for aggregate poverty measures for the developing world over the period 1987-93. They estimate that the percentage of the population consuming less than \$1/day at 1985 international prices (with currency conversions at purchasing power parity) decreased only slightly over this period, from 30.7 per cent in 1987 to 29.4 per cent in 1993 implying that the numbers of people living under \$1/day rose from 1/23 billion to 1 32 billion over this period (\$1/day is about equal to India's urban poverty line ) The gains to the poor in east and (less so) south Asia were roughly counter-balanced by the losses in other regions, notably Sub-Saharan Africa, Latin America and Eastern Europe and Central Asia
- 2 Contrast, for example, Ahluwalia's (1978:320) conclusion that "there is evidence of some

trickle down associated with agricultural growth" with Saith's (1981:205) claim that "there can be little doubt that current growth processs have served as generators of poverty"; both were using data for India over roughly the same period (1957-73). The debate continues; in recent literature on India one can find claims that "rapid agricultural growth has benefited all classes of the poor" [Singh 1990] and "acceleration in agricultural growth by itself is unlikely to make a dent in rural poverty" [Gaiha 1995;285].

- 3 For an overview of the theory and evidence on the effects of adjustment on the poor see Lipton and Ravallion (1995, section 5.3). In the Indian setting, see Ravallion and Subbarao (1992).
- 4 See Datt (1996), Ozler et al (1996), Ravallion and Datt (1995, 1996), and Datt and Ravallion (1996) Later we identify which paper is most relevant to each topic covered here
- 5 A number of the popular methods of making poverty comparisons over time and space do not satisfy this consistency requirement, see Ravallion (1994) for further discussion
- 6 For further discussion of this point see Sen (1987), in the context of India also see Dreze and Sen (1995)
- 7 See Planning Commission (1993)
- 8 We compared this difference in the poverty lines to independent estimates of the urbantural cost of living differential. For 1973-74, Bhattacharya et al (1980) estimated that the cost-of-living for the poor was 16 per cent higher in urban areas, exactly the same (to the nearest integer) as the differential in poverty lines. So it can be en argued that the planning commission's urban and rural poverty lines represent the same standard of living, and (hence) that we are making consistent comparisons of absolute poverty between urban and rural areas. For further discussion see Ravallion and Datt (1996)
- 9 For the urban sector after August 1968, the all-India consumer price index for industrial workers (CPHW) is used as the deflator. For the earlier period, the Labour Bureau's consumer price index for the working class is used, which is an earlier incarnation of the CPHW albeit with a smaller coverage of urban centies (27 against 50) The rural cost of living index series was constructed in three parts. For the period since September 1964, the rural cost of living index is the all-India consumer price index for agricultural labourers (CPIAL) published by the Labour Bureau. For the period September 1956 to August 1964 (for which an all-India CPIAL does not exist), a monthly series of the all-India CPIAL was constructed as a weighted average of the state-level CPIALs, using the same statelevel weights as those used in the all-India CPIAL published since September 1964 For the initial period August 1951 to August 1956, forecasts were obtained from a dynamic model of the CPIAL as a function of the CPHW and the wholesale price index. Our new CPIAL series also dealt with another problem which has to do with the fact that the Labour Bureau has used the same price of firewood in its published series since 1960-61 Firewood is typically a common property resource for agricultural labourers, but it is also a market good, and so the Labour Bureau's practice is questionable. Our CPIAL series

- corrects this by replacing the firewood subseries in the CPIAL by one based on mean rural firewood prices (only available from 1970) and a series derived by assuming that firewood prices increased at the same rate aall other items in the fuel and light category (prior to 1970). For details see Datt (1996)
- 10 These are fixed weight price indices. Thus, they ignore substitution in response to shifts in relative prices. To test sensitivity to this Ravallion and Subramanian (1996) compare poverty measures for India with and without an allowance for substitution effects consistent with demand behaviour, as modelled by a set of full rank Gorinan Engel curves. Ignoring substitution matters far more for some measures and applications than others. It leads to overestimation of inequality, but level effects on poverty measures are generally small and turning point errors are rare.
- 1 These are members of a class of measures proposed by Foster, Greer and Thorbecke (1984). A transfer of income from a poor person to a poorer person (for example) will not alter either the head-count index or the poverty gap index, but it will decrease the squared poverty gap index. Furthermore, the squared poverty gap index satisfies the subgroup consistency' property, namely that if poverty increases in any subgroup (say the urban sector), and it does not decrease elsewhere then aggregate poverty must also increase [Foster and Shorrocks 1991].
- The poverty measures are calculated using parameterised Lorenz curves. We use either the beta Lorenz curve of Kakwani (1980) or the general quadratic model of the Lorenz curve of Villasenor and Ainold (1989), depending on which fits the data best (both satisfied the theoretical conditions needed for a valid Lorenz curve in all survey rounds for both sectors) Using the formulae derived in Datt and Ravallion (1992), the poverty measures are calculated from the estimated parameters of the Lorenz curve and the mean per capita consumption expenditure. A number of checks are made on the results, including both the theoretical conditions for a valid Lorenz curve, and consistency checks, such as that the estimated value of the head-count index must be within the relevant class interval of the published distribution. The estimation technique has been set-up in a user-friendly computer programme 'POVCAL' [Chen, Datt and Ravallion 1991] which is available or request, so interested readers can read!! y check our calculations and their sensitivity to our
- 13 A complete descriptions of the data set and all sources can be found in Ozler, Datt and Ravallion (1996) with an accompanying se of diskettes.
- 14 The first subperiod is marked by three significant peaks in poverty around the years 1953-55 (rounds 7,8), 1956-58 (rounds 11 12, 13), and 1966-68 (rounds 21, 22), the las of these coinciding with the worst drough in the post-independence period.
- 15 Based on poverty measures averaged ove NSS rounds, weighted by the duration of the survey.
- 16 The absence of fluctuations in poverty ove the period 1975-85 may be somewhat illusor, as we have only two NSS surveys in the intervening period, viz, those for 1977-78 and

- 1983. In particular, we do not have poverty estimates for the two drought years 1979 and 1982.
- 17 The Indonesia estimates are from the nationalsocio-economic surveys (SUSENAS) done by Indonesia's central bureau of statistics. The 1970 number is from World Bank (1990, Table 3.2), the 1993 number is our estimate from the 1993 SUSENAS using the same real poverty line. The consumer price index was used to convert to constant prices.
- 18 The estimates in Table 2 are based on regression of the percentage change in the poverty measures against the percentage change in consumption or net product per person using 33 household surveys spanning 1951-1991 for the surveys-based mean consumption, and 23 surveys spanning 1958-91 for consumption or income from the national accounts. All regression coefficients were statistically significant at the 1 per cent level or better, and all regression comfortably passed all the standard specifications tests. For full details see Ravallion and Datt (1996).
- 19 Using the methodology outlined in Datt and Ravallion (1992).
- 20 The observed poverty measures are subject to large fluctuations from one NSS round to another; this is particularly true of some of the shorter initial NSS rounds The cumulative series can thus be somewhat misleading for arbitrary choice of the starting point. To deal with this problem, we selected NSS round 6 (May-September 1953) as the reference date for the first decomposition; the poverty measures for this round reasonably approximate the average poverty measures for 1951-55 (weighted average for rounds 3-8, with weights proportional to the number of months in the survey period of each round). The graphs of the decompositions for NSS round 9 onwards in Figures 2 and 3 can thus be interpreted as referring to the cumulative change in poverty (and its components) since the mid-1950s
- 21 Sec Datt (1996) for details.
- 22 See Ravallion and Datt (1996) for details on the methods used.
- 23 This has long been recognised in discussions of poverty in India, and the Second Plan was criticised for this reason at the time (see, for example, Vakil and Brahmanand's (1956) comments on the Second Plan) For a recent discussion in the Indian context see Dev et al (1992). Recent affirmations of the importance of labour-demanding growth to poverty reduction in developing countries include World Bank (1990), Eswaran and Kotwal (1994) and Lipton and Ravallion (1995)
- 24 For details on methodology see Ravallion and Datt (1995). On the link between real wages in agriculture and rural poverty measures for India also see van de Walle (1985).
- 25 See Datt and Ravallion (1996) for more detail.
- 26 Some of national samples, particularly in the 1950s, were too small to allow reliable estimation at the state level, so this part of the analysis focused on the period from about 1960 onwards.
- 27 For discussion of the range of experiences in direct interventions for poverty reduction see Kakwani and Subbarao (1993), Dreze and Sen (1995), and Vyas and Bhargava (1995)

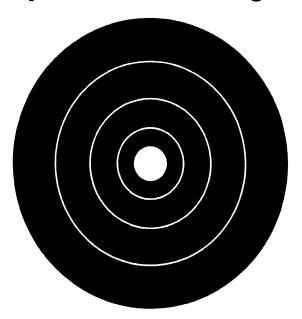

- and other papers in the October 14-21, 1995 issue of the Economic and Political Weekly. Progress does not appear to have been even within states either, though our data do not allow us to disaggregate further. For evidence on changes between 1972-73 and 1987-88 at the level of the NSS regions see Dreze and Srinivasan (1996).
- 28 The estimated model also included a correction for serial correlation in the residuals (allowing for the uneven spacing of the NSS rounds, requiring non-linear estimation methods); see Datt and Ravallion (1996) for details.
- 29 For full details on the estimated models and various specification tests see Datt and Ravallion (1996).
- 30 Kerala stands out as an unusual case in India, given its high level of human resource development, including at the beginning of the period under study. [For further discussion of Kerala's achievements in this respect see Dreze and Sen 1995] However, even if we drop Kerala from the regressions, the initial conditions in human resource development (and indeed all other variables in our model) remain significant [Datt and Ravallion 1996]. Their effect is not just due to Kerala.

# Our management philosophy: Expand on our strengths

# Our market objective: Be right on target

I.T.C. Limited with a turnover of Rs 5,200 crores is one of India's largest, diversified, professionally managed enterprises.

Employing thousands of people directly and many more indirectly, ITC is a dynamic corporate entity forever in the pursuit of excellence, gathering strength and support from over 2,00,000 shareholders, 1.5 million retailers and 5,00,00 farmers. Its distribution network is among the largest in the country. It touches the lives of over 1% of India's rural population and is deeply rooted in the heart of India.

With offices in seven countries across the world, ITC has formed successful strategic alliances with international chains. International competitiveness is at the core of its operations.

This then is ITC's philosophy. Of growth on target.

New horizons, new hopes.

# **Poverty Estimates and Indicators**

### **Importance of Data Base**

#### M H Suryanarayana

This paper emphasises the importance of the data base in any discussion of poverty and identifies the major data gaps for policy studies. Beginning with the identification of the poor based on a measure of standard of living and a minimum norm and going up to the final stage of policy prescription, an awareness of the data base and the constraints it imposes on interpretations is crucial. Conventional approaches to poverty identification and measurement presuppose a stationary economy. But in an economy subject to changes in institutional parameters involving increasing commercialisation of product markets and growing casualisation of labour markets, as in India in recent years, the conventional approach can yield misleading results and policy prescriptions.

#### I Introduction

IDENTIFICATION of the poor and estimating the magnitude of poverty has received considerable attention during the reform programme for stabilisation and structural adjustment in different countries all over the world. Identification of the poor is important for effective targeting of various poverty alleviation programmes and safety nets so as to ensure their budgetary cost effectiveness in minimising the social cost of the reform programme. The magnitude of poverty has to be estimated for assessing the budgetary implications of the various safety net programmes and for evaluations of these programmes. As part of its efforts to minimise the social costs of the reform programme and the associated budgetary costs, the Indian government is also seized of the problem of identifying the poor, the magnitude of poverty and their cost-effective solutions. Ever since the reform programme began in July 1991, there has been considerable debate on efficient targeting of the various poverty alleviation programmes and safety nets, the public distribution system in particular.

As for any empirical policy study, effective solutions for the issues raised above presuppose an efficient information set. The information requirement varies with the questions raised and the proposed objectives of policies. If the questions are who are the poor, what is the magnitude of poverty and if the objective is to examine the welfare levels and consequences of policy changes, then a measure of economic (material) welfare or standard of living would be the relevant variable. If the question is what makes the people poor and the purpose is to formulate efficient policies for poverty alleviation then causes and correlates of poverty assume relevance. In either case, identifying the poor assumes a lot of importance.

Poverty is generally defined as the inability to secure a minimal level of economic

welfare This raises the questions: How to measure economic welfare? What constitutes a minimal norm or poverty criterion? The answers for these questions depend, in turn, upon the scope for policy action as dictated by government's resource constraint, social consciousness and academic perception of the problem. This is because economic welfare may be measured in terms of different variables: per capita income, per capita consumer expenditure, per capita food consumption, Engel ratio, calorie intake, anthropometric measures or basic needs. Poverty groups identified, estimates of their magnitude and policy measures designed will vary depending upon the economic welfare measure chosen for defining poverty. All through the post-independence period the focus of academic research as well as government policy reports in India has been on absolute poverty or the proportion of the poor population. Absolute poverty is estimated on the basis of private consumer expenditure with reference to a poverty line defined on a normative calorie intake basis. Even when we address such a narrow set of questions, the scope for misinterpretation of statistical measures by disregarding data considerations is considerable and hence, the question of data base is quite important.2 The most widely used data base for poverty studies in India is the household consumer expenditure data collected by the National Sample Survey Organisation (NSSO). Conceptually, consumer expenditure as a measure of standard of living has the advantage that it is amenable to welfare interpretations subject, of course, to the limitation that it does not consider the welfare derived from leisure and pure public goods. In a predominantly monsoon dependent agricultural economy like India where agriculture constitutes the source of livelihood of about two-thirds of the population, consumer expenditure measure has an additional advantage that it may not reflect the periodic variations in income. But, when it comes to empirical verifications it bristles with many problems. Empirically, conclusions from comparison of real consumer expenditure levels would vary depending upon how different items of consumption are valued. In a country where income distribution is not optimal, market price is not a proper welfare measure. In addition, as regards the NSS data base, there are a number of statistical questions regarding its reliability. There are other issues like sample data presentation, tabulation and institutional parameters which have been ignored in the poverty studies resulting in misleading inferences.

Even though the government has been carrying out poverty alleviation programmes, much remains to be done on the povertyidentification and measurement fronts for policy operational purposes. This is so in spite of the policy emphasis on costeffectiveness of the poverty alleviation programmes.1 Cost-effectiveness can be achieved either by maximising benefits to the poor for a given budgetary cost or by minimising the cost subject to a poverty alleviation target. One approach to achieve cost-effectiveness is by 'better targeting' of programmes, i.e. by maximising the coverage of the poor and minimising the leakages of benefits to the non-poor. How do we pursue such goals and formulate different policy actions? Different country experiences including that of India have shown that identifying the poor for purposes of targeting by 'means-test' is administratively costly. This is because people have an incentive to under-report incomes so as to secure more benefits than they are eligible for.4 If so, targeting is desirable so long as the administrative cost of identifying the poor does not exceed the saving involved in excluding the non-poor. This problem is sought to be overcome by 'indicator targeting', i.e. by making eligibility for benefits conditional on correlates of poverty, such as land holding, caste, or place of residence. In that case, we need to ask, what are the appropriate indicators or correlates of poverty and their implications? What are the data requirements in such a context?

This paper addresses some of these questions pertaining to the two themes of poverty estimates and targeting of programmes. The paper is organised as follows. Section 2 deals with the first set of issues on data base for estimating the magnitude of poverty in India, i.e., consumer expenditure data collected by the NSSO, its limitations, scope for wrong inferences and the need for an integrated approach. Section 3 deals with the shift in emphasis towards targeted welfare programmes for the poor and their implications for methodology and data base. The final section sums up the paper.

# II Data Base for Poverty Estimates

Poverty analysis in India is generally carried out using private household consumer expenditure as a measure of standard of living.6 Income/consumer expenditures are sufficient measures so long as they include own production. Even then they capture only certain economic aspects of welfare. They do not take into account other dimensions of welfare like health, life expectancy, literacy, access to safe drinking water, public goods or common property resources. In fact, these other dimensions are important since they do not remain the same over time in the course of economic development. Poverty, defined and estimated using a narrow concept of standard of living, has its own limitations in the context of a developing economy.

Much has been written about the adequacies and inadequacies of the NSS methodology and their implications for estimates of consumption aggregates and distributions [Dandekar and Rath 1971; Dandekar and Venkataramaiah 1975; Iyengar and Bhattacharya 1975; Kadekodi 1992; Minhas 1988; Mukherjee 1986; Srinivasan and Bardhan 1974; Suryanarayana and lyengar 1986; Tyagi 1982; Vaidyanathan 1986a, 1988]. Most of these studies examine the question of reliability of the NSS estimates of the underlying population parameters by different statistical criteria. This section of the paper examines the implications of some of the features of the NSS estimates of consumer expenditure for poverty estimates and their interpretation in the course of development.

The NSS is a socio-economic enquiry carried out in the form of successive rounds. The period of enquiry has been varying across rounds and has varied from a few weeks to months. During these rounds, the NSS collects information on various socio-economic aspects of households, household consumption being one of the most important. The data are collected on the basis of

interviews of households. The households are selected following simple random sampling. The sample design is stratified and two-stage in both rural and urban sectors. The stratification of rural areas is with respect to homogeneity of population density, cropping pattern, etc, while that of urban areas is with respect to population sizes of towns and cities. The first stage units are villages in the rural sector and urban blocks in the urban sector. The households constitute the second stage units in both the sectors.

The NSS concept of consumer expenditure includes all the non-productive expenditure incurred by the households. It includes consumption out of home-grown produce, gifts, loans, etc. Data on perquisites like food in the employer's house are not included in the NSS estimates of consumption of the employee households. This must have resulted in underestimation of foodgrain consumption by the employee households who in the rural sector are generally poor landless households. In-kind wage payments, including prepared food at the employer's home, used to be quite common during the 1950s and 1960s. The consequent underestimation of foodgrain consumption by the labour households must have resulted in overestimation of poverty, particularly distributionally sensitive measures like the Sen index [Sen 1976] and the P measure [Foster-Greer-Thorbecke 1984]. According to the second agricultural labour enquiry of 1956-57, agricultural labourers received wage payments in kind for about 50 per cent of the mandays worked.8 As studies [see, for instance, Vaidyanathan 1986b] have shown, there has been increasing landlessness and casualisation of labour since the mid-1970s. which must have resulted in increasing market dependence of the poor. Such progressive market dependence of the landless poor must have involved increasing monetisation of the labour market and hence, also that of their consumption. As a result, the extent of underestimation of foodgrain consumption by the poorer households and hence, overestimation of poverty must have declined. This is one factor that has to be taken into account in interpreting the observed declining trends in poverty estimates since the mid-1970s.

The NSS does not take into account the imputed rental value of owner occupied houses. This would affect estimates of consumer expenditure inequality measures and hence any estimation of poverty based on the inequality parameter. The consumer expenditure data are collected by the NSS using a moving reference period by which the interviewing of sample households is spread over the year. This introduces a seasonality bias into the data. Its implications have been well documented in the literature. What is little recognised is that such a

procedure also superimposes price variation on actual variation in consumption during a period of rising prices. This will affect estimates of poverty and inequality based on consumer expenditure distribution. This must have been a serious problem for estimates of poverty and inequality for the 1960s and 1970s when there was considerable interyear price dispersion caused by restrictions on inter-state foodgrain movements [Ray 1970]. This is one aspect which has not been taken into account in the studies on trickle down of agricultural growth in rural India [Suryanarayana 1996b].

The NSS surveys are generally based on the consumer expenditure schedules. The NSS surveys were integrated household surveys during the 19th to 25th rounds inclusive. That the NSS used integrated schedule only for some select rounds has affected adversely the inter-temporal comparability of its estimates of consumer expenditure and hence poverty estimates. Available evidence indicates that people under-reported their consumption during the rounds covering the integrated household surveys [Mukherjee and Saha 1981; Suryanarayana 1996b]. Accordingly, the NSS estimates of consumer expenditure for these years are substantially lower than the National Accounts Statistics (NAS) estimates. This could be one reason why NSS based poverty estimates show substantially higher levels of poverty during the 1960s. Thus, such questions on intertemporal comparability of data base affect inferences on trends in poverty.

The data base also gets affected by the method of valuation. Poverty estimates based on such data using conventional statistical deflators may be valid in a given stationary context but loses its meaning and relevance when the context itself undergoes a change. For instance, the NSS distinguishes between consumption from homegrown stock and that from market purchases, and values the former at farm harvest prices and the latter at market retail prices. In a semi-monetised economy where a substantial segment of the rural population consists of subsistence farmers, this approach may be valid. For instance, consumption out of home grown stock accounted for 50.9 per cent of total food grains consumption in the rural areas and 7.15 per cent in the urban areas during 1964-65 [GOI 1972:4]. In the development context, as observed in recent years in India, institutions, labour markets, and production conditions change. As already noted, with progressive market dependence of the poor there must have been increasing monetisation of consumption. By the NSS method of valuation, the same amount of physical consumption would get exaggerated in nominal terms due to changing price weights, whereby an increasingly larger part of consumption is valued at (generally) higher retail prices. On the other hand, with the green revolution, there have been changes in the crop composition of foodgrain output from the cheaper inferior cereals to superior but costlier superior cereals like rice and wheat involving a decline in per capita availability of coarse cereals necessitating a shift in consumption patterns in favour of the latter. In such a context, inferences on trends in measures of poverty based on estimates of consumer expenditure obtained by dual valuation can be misleading [see, for details, Suryanarayana 1995].

Such questions are fundamental for any empirical study on poverty during the development process. Few studies have addressed these questions or cared to relate them to their main query. Both are needed because a poverty measure, like any other descriptive statistical measure, is a conditional measure, i e, conditional on the prevailing structural features like market, production and other institutional parameters. Unless one considers these conditional parameters, one is likely to end up making wrong inferences. The following is an example. The very concept of poverty line and its updating by simple price ratios does not make sense since with changes in structural parameters the base year poverty line is not valid any longer. Similarly, various poverty measures which are supposed to aggregate and summarise characteristics of the poor will not convey the dynamics of underlying changes. For instance, Ahluwalia (1978) does not examine these institutional parameters; instead Ahluwalia regresses poverty estimates on agricultural production and confirms trickling down of growth to the poor. But actually due to structural changes in production conditions and labour markets, cereal consumption of the general population and some poorer sections has actually declined contrary to what one would expect during a period of poverty reduction [Suryanarayana 1995]. A similar limitation applies to the recent debate on economic reform and increase in poverty. Studies, using poverty measures, have not examined how far these measures summarise the dynamics underlying the explanation put forward by them. For instance, Tendulkar and Jain (1995) make estimates of poverty for 1990-91 and 1992 They find that between 1990-91 and 1992, there was a substantial increase in rural but only a marginal increase in urban poverty. They contrast these rural and urban changes and attribute the increase in rural poverty to bad harvest. This is because economic reform measures in the initial years involved fiscal contraction and import compression which must have adversely affected the urban sector first. Hence, urban poverty should have increased more sharply than the rural. That this did not happen was,

according to them, due to the decline in agricultural production particularly coarse cereals along with speculative hoarding by traders and farmers which resulted in an increase in cereal prices, reducing thereby the economic entitlement of only the rural poor. The urban poor did not suffer to the same extent because they were relatively better protected by the urban-biased public distribution system (PDS). Thus, Tendulkar and Jain conclude that economic reforms contributed indirectly and was not a major cause of increase in rural poverty. They arrive at these conclusions without examining how far the data or the summary measure reflects the postulated economic processes. They build up poverty estimates and their explanations from diverse non-comparable data sources. As shown in Suryanarayana (1996a), the price indices used in obtaining rural-urban poverty estimates are outdated and non-comparable. Further, the NSS data itself shows that percentage reduction in cereal consumption was more in the urban than in the rural areas in majority of the states and particularly in the most urbanised states of Maharashtra, Gujarat and West Bengal. Thus, the statistical details underlying the summary statistics do not provide any support for the explanation put forward by Tendulkar and Jain. Instead, they support the contrary, by their own reasoning. These two illustrations show the importance of data base and its verification in any discussion on poverty analysis, explanation and their policy implications.

There is another limitation stemming from the fact that poverty estimates based on consumption data are conditional measures, namely, these consumption estimates do not take into account the access to common property resources10 and their importance for the poor. For instance, as Jodha (1990) shows, in dry regions of India in 1982, about 84 to 100 per cent of the poor population depended on common property resources for fuel, fodder and food. Over time, there has been a decline in area, productivity and maintenance of these common property resources due to large-scale privatisation, inappropriate policies and programmes for productivity improvements, increased commercialisation resulting in overexploitation and resource degradation, etc. This has resulted in reduced reliance of the poor on common property resources and hence, increased cost of achieving the basic minimum level of living. Therefore, the current approach of updating the poverty line by adjusting for only price changes may not be valid; instead the very poverty line may have to be redefined before obtaining the conditional poverty measures. Accordingly solutions for poverty eradication may differ and get varying emphasis.

Further, the NSS estimates of consumer expenditure would serve the purpose so long as the questions to be addressed are limited and confined to a poor economy subject to serious budget constraint which restricts the policy options and size. In such a context, calorie based 'minimal' poverty line reflects an approach to poverty alleviation which is concerned with eradication of mass hunger and starvation. Accordingly, the studies in India have all along considered a calorie based poverty norm and confined themselves to measuring absolute poverty. This explains why factors other than hunger got low priority in policy formulations, and plan achievements with respect to primary education, primary health, etc., have remained quite modest. Therefore, it is time that we defined a poverty line with adequate provision for education, nutrition, health, housing, etc. This would call for data on various socioeconomic aspects of rural households.

But, even access to public services and common property resources vary across households. No single survey data gives information on all these aspects. This would raise questions regarding comparability and integrability of the data sets on various aspects. For instance, the NSS estimates of household size based on the survey of social consumption is quite different from that based on the consumer expenditure survey for 1986-87. The average household size is 5.26 in rural all-India and 4.79 in urban all-India as per the NSS annual consumer expenditure survey but 5.20 and 4.90 respectively as per the NSS social consumption survey [GOI 1989 and 1990]. Therefore, even though there are various NSS surveys of different socio-economic aspects of households, there are questions regarding the extent to which such data can be combined to throw up a complete and integrated picture of poverty.

Policies for a sustained solution for poverty can be formulated only with an adequate understanding of the nature and causes of poverty. This calls for a distinction between chronic and transient aspects of poverty Such aspects can be examined only with panel data. Of course, it will raise questions as to how far the results based on such panel data can be generalised for the population Their value is essentially from their policy implications and suggestions. One approach to overcome such constraints could be to examine qualitative aspects of economic life. Jodha (1988) shows that there is a need for supplementing macro investigations with micro studies. Of course, often they end up with contradicting conclusions. Jodha explains such contradictions in terms of methodological deficiencies of the micro approaches. Such deficiencies are due to (i) restrictive concepts and categories used for identifying rural realities; (ii) restrictive

norms and yardsticks used for assessment of rural realities; and (iii) communication gaps between the researcher and the respondent. Jodha (1988) illustrates the need for supplementing researcher's approach by the respondent's approach, citing results on incidence of poverty in two villages of Rajasthan during 1963-66 and 1982-84. Poverty identification was done by the conventional approach using the income criterion and by qualitative indicators of economic well-being. Households that had become poorer by the income criterion were actually better off by the qualitative measures of economic well-being. The villagers measured the changes in their economic status in terms of the following criteria: (i) decline in their reliance on the traditional patrons, landlords, and resourceful people for sustenance, employment, and income; (ii)decline in dependence on low pay-off jobs; (iii) improved mobility and liquidity position; (iv) shifts in consumption patterns and investment in durables. The changes reflected by these qualitative indicators are essentially the result of gradual changes over a long period of time unlike those reflected by the changes in income which capture only the transitory components.

Infact, the very purpose of the development process and policies is to achieve such improvements in economic status and opportunities and any analysis of changes in poverty has to consider such improvements. This underlines the need for supplementing information on consumption by other qualitative indicators so as to arrive at correct inferences. One effective solution seems to be a decentralised approach with the participation of the local people in identifying the poor, determining solutions for the poor and targeting them for the poor.

# III Poverty Alleviation Programmes and Indicator Targeting

How do we identify the poor by some simple indicators so as to ensure targeting

of benefits only to the poor? The Government of India set up a working group to evolve an acceptable methodology for identifying the poor through criteria alternative to per capita income/calorie requirement. The working group considered the household as the unit of enquiry for identification [GOI 1985b]. The group sought to identify poor households by characteristics "which are simple, easily verifiable and easily amenable to collection and recording of information about them without observational errors". The list of household characteristics considered for field survey for identification of the poor is given in appendix I. However, the actual study was based on the results of the survey conducted by the directorate of economics and statistics, Maharashtra of the standard of living of the rural households during 1982-83. This was a re-survey of the same set of households can vassed during the 32nd round of the NSS during 1977-78. Essentially the group attempted a dichotomous classification of the households into poor and non-poor on the basis of not only consumer expenditure but also other household characteristics. The efficiency of classifying households as poor or otherwise by other characteristics was assessed by the extent of mis-classification vis-a-vis that by consumer expenditure.

The analysis was conducted for the sample data from the two districts of Aurangabad and Solapur. For example, one exercise was based on a sample of 171 households from Aurangabad. The study found that six characteristics, namely, (i) land possession, (ii) irrigated land, (iii) type of wall, (iv) possession of sofa-cot, (v) floor area per capita, and (vi) possession of account in bank/post office, were highly correlated with per capita consumption expenditure. A comparison of the classification of households into poor and non-poor by these characteristics with that by consumption expenditure by the discriminant analysis showed that the overall mis-classification was as high as 34.5 per cent. Among the six characteristics considered, land possession and irrigated land had low correlation with per capita expenditure. Hence, the exercise was repeated by dropping these two characteristics but the extent of misclassification reduced to only 26.9 per cent. A similar exercise was carried out on the basis of a sample of 300 households from Solapur. The exercise considered 41 characteristics consisting of 24 qualitative characteristics (converted into quantitative form by standardisation assuming normal distribution), five quantitative characteristics and 12 new characteristics constructed from the sample data. From these, 14 characteristics having high correlation with per capita expenditure but low correlation among themselves were selected for discriminant analysis.11 The study found the extent of mis-classification was about 35 per cent under two alternative threshold values and the results did not change substantially even for analyses based on (five-year) lagged and current per capita consumption. The group concluded that there is no alternative to the identification of the poor except by annual income or expenditure. Of course, when the estimates of per capita consumption itself has so many limitations, one may raise questions regarding the classification by expenditure criterion as the reference classification. It is also difficult to justify the assumption of normality while transforming the attribute values of qualitative characteristics into standard normal variate. This seems to be a major limitation of the exercise. For, normality of variables is a basic assumption of the discriminant analysis, which is very sensitive to the fulfillment or otherwise of the basic assumptions.

Attempts have been made in India for targeting some of the poverty alleviation programmes on the basis of the means-test. For example, the ministry of rural development identifies household by income criterion for targeting the benefits of the Integrated Rural Development Programme (IRDP). The target group is the rural poor consisting of scheduled castes, scheduled tribes, agricultural labourers, marginal

farmers with annual income less than a specified threshold level (Rs 6,400 per annum per family in 1987) and bonded labour families. The beneficiaries are identified in two stages. To begin with, a family income survey/census is carried out to ascertain family income from all sources. In the second stage, a list of all potential beneficiaries is prepared. The list is further screened by the gram sabha or in the general meeting of the village residents. But, this is not a fool-proof criteria. Studies by the National Bank for Agriculture and Rural Development (NABARD) and programme evaluation division of the planning commission have shown that there are leakages of IRDP benefits to ineligible households.12

Recent estimates of distribution of number of beneficiary households per thousand households of different poverty alleviation programmes across economic classes, occupational groups and social classes also show considerable leakages to the nontargeted groups. The NSSO collected information on receipt of IRDP assistance. participation in public works, etc, during the 43rd round survey on consumer expenditure. The enquiry, among other things, was about households which received IRDP assistance sometime during the last five years, those which participated in public works during the last 365 days and their consumption during the month preceding the date of survey. Tables 1 to 4 provide the proportion of beneficiary households across different socio-economic status. The results on distribution of proportion of IRDP beneficiary households across monthly per capita expenditure (MPCE) classes show that they are uniformly spread over all expenditure classes (Table 1). Since IRDP benefit refers to assistance received some time during the last five years while MPCE relates to the month preceding the survey, the results cannot be treated as unambiguous evidence of misallocation of IRDP since the observed pattern could also be due to the very success of IRDP in poverty alleviation. Therefore, the question on IRDP targeting should be verified further and one option would be to examine the spread of beneficiary households across six different 'land possessed' classes of households (Table 2). The data bring out that IRDP benefits have been conferred on all classes of households, and not on only the poorer groups. The statewise data show that in Andhra Pradesh, Assam and Bihar, the proportion of beneficiary households increases with size class of land possessed; but in Kerala, Punjab and Himachal Pradesh the proportions of beneficiary households are more in the lower classes of land possessed [GOI 1993:101]. The findings on IRDP leakages to noneligible households get only confirmed by the data on distribution of beneficiaries across other socio-economic categories (see Tables 3 and 4).

During the ongoing economic reform programme, there is renewed stress on the need for cost-effective safety nets to protect the poor without exacerbating the government budget deficit. This has called for targeting of various welfare programmes like the PDS. Any targeting exercise presupposes identification of the poor by means test or some other criteria. In the context of the PDS reform, experts have argued for commodity based targeting also by re-orienting the PDS in favour of coarse cereals, little realising that the consumption patterns of even the poor have undergone a change against coarse cereals and other

inferior food items. This has happened partly due to availability constraints, partly due to increased incomes and hence entitlement, and due to greater market exposure [see Suryanarayana 1995].

Similar suggestions for indicator targeting have been made with respect to poverty alleviation programmes. Experts have recommended employment-oriented strategy towards poverty alleviation on the ground that it permits self-selection of the poor and hence leakages to the non-poor will be minimum. This is based on the understanding that there is considerable scope for targeting by setting the wages at the reservation level in programmes like public works. The reservation wage for unskilled workers being

Source GO1 (1993)

inversely related to poverty, only the poor are expected to participate in such programmes, whereas the opportunity cost of participation is higher for the non-poor. However, Indian experience even with indicator targeting of poverty alleviation programmes has not been that successful. One important reason seems to be the faulty design of such programmes like guaranteed minimum wages and not reservation wages. The NSS results about the beneficiaries of public works programmes from the 43rd round survey are as follows. As regards public works beneficiaries, the NSS considers a household as a participant in public works during the reference period (365) days if at least one member of the household has worked for 60 days or more during the reference period. From Table 1, it can be seen that the proportion of household beneficiaries per 1000 households declined from 81 for the poorest expenditure class to 42 for the richest expenditure group for all-India, For Orissa, Bihar, Assam, Tamil Nadu, Andhra Pradesh and Uttar Pradesh, no such declining trend can be observed. The proportion of beneficiaries is higher in lower expenditure classes only in Gujarat, Rajasthan and Maharashtra (GOI 1993, 104). The data on household classification by classes of land possessed for all-India show that the proportion of household participation is higher for groups possessing more land than those with less land (Table 2). When the public works participation is examined by occupation type of households, the all-India estimates show the participation to be highest among other labour households tollowed by agricultural labour households (Table 3). But in Tamil Nadu, West Bengal and Assam, it is the 'self-employed in nonagriculture' who seem to have benefited most than other categories. In all other states, 'other labour' households' participation is proportionately more; in Punjab and Maharashtra 'agricultural labour' and 'other labour' households participated more or less equi-proportionately [GOI 1993:104]. The data by social group, shows the SC/ST households to have benefited much more than 'other households' (Table 4). In sum, the evidence presented above brings out two salient features: (i) They indicate considerable leakages of benefits of poverty alleviation programmes like the IRDP and public works and hence call for their reform on the identification front for effective targeting. This would improve costeffectiveness of these programmes and enhance the poor's economic access to food; and (ii) the pattern of leakages across different socio-economic categories vary across states suggesting that there is no single correlate or factor by which issues regarding targeting can be considered across the entire There is also a need for studies to evaluate strategies and policies for poverty alleviation and their micro and macro implications in view of the current emphasis on efficient utilisation of resources. Even though there have been such studies based on computable general equilibrium (CGE) models, they have their own limitations. One major merit of such models is supposed to be their ability to endogenise the price vector and take into account the substitution effect of relative price changes. These CGE models to the rural

sector in spite of the fact that a substantial portion of the rural resident households are subsistence and surplus farmers and their market participation rates for food consumption are very low. As per the available estimates, market participation rates for the all-India total rural population for rice and wheat were 57.19 and 30.2 per cent respectively in 1986-87 [GOI 1990]. For these households, an increase in the price of a staple commodity has not only a negative substitution and income effect but also a positive profit effect. Hence, there is a

#### INDIA'S ECONOMIC REFORMS 1991-2001

VIJAY JOSHI / I.M.D. LITTLE

Vistalia V

In 1991, India embarked on major economic reforms that have the potential to transform its future economic development. This book, written by two distinguished analysts of the Indian economy is a comprehensive evaluation of these reforms. It analyses the progress made in the last five years, considers the likelihood of its continuance and suggests an agenda for the future.

Essays in Fiscal and Financial Sector Reforms in India RAJA J. CHELLIAH

This topical book has as its background the ongoing programme of economic reforms in India. India provides a lucid analysis of the logic and basis of the entire reform agenda. Concentrating on fiscal and financial sector reforms. Dr Chelliah examines in detail the steps needed to complete the reform process initiated in 1991. In this context he presents a comprehensive analysis of the fiscal situation with special emphasis on controlling the fiscal deficit

Freeing the Economy

JAGDISH BHAGWATI

This volume, written in a style accessible to the general reader, provides an overview of the Indian development experience over the last forty years. It argues that the protectionist regime of the sixties and seventies stifled economic initiative and development, culminating in the fiscal crisis of the late eighties. Some of the factors which explain India's poor performance, including the absence of compulsory education, bureaucratic interference in entrepreneurial decisions and the low productivity of India's saving ratio, are also analysed

Specimenton error mirorres in estimating a traditional demand model, which cannot take into account the profit effect, for the rural sector. The specification error must have peen quite serious for India as most of these traditional demand models are estimated on the basis of the NSS data collected using a moving reference period spread generally over an agricultural year. Actually, consumer preferences in the rural sector have to be specified and estimated in terms of an agricultural household model that takes into account the interdependence of production and consumption decisions. Studies [Singh et al 1986] have shown that such specification errors really matter and the results differ depending upon whether the profit effect is considered or not. Estimates of own price elasticities of demand for agricultural commodity obtained using the two alternative approaches, that is, traditional demand and agricultural household models, differed significantly with respect to size for Japan, Thailand and Sierra Leone and with respect to both size and sign for Taiwan, Malaysia, Korea and Northern Nigeria. While the own price elasticity estimates obtained by the traditional demand models show negative consumer responses to agricultural commodity price changes for all the countries considered, those by agricultural household models show much smaller negative responses for Japan, Thailand and Sierra Leone but positive consumer responses for the remaining four countries [Singh et al 1986:27]. Equally striking are the differences in estimates of elasticities of demand for non-agricultural goods with respect to the price of agricultural goods. Cross price elasticities based on traditional demand models are small and negative because of negative income effects; those obtained from the agricultural household models are positive and large because of the positive profit effect. Unless the data required for such a type of specification and estimation are available, it is not possible to make accurate analysis of welfare consequences and policy implications of various market intervention and poverty alleviation programmes. But, even while using the traditional demand models for the general equilibrium analysis, some of the available CGE models are based on characterisation of consumer preferences by the Stone-Geary utility function and hence the Linear Expenditure System.14 The underlying preference structure of the Stone-Geary utility function is additive, separable and linear. Demand models based on additive separability of preferences cannot account for substitution effects of relative price changes and price elasticities based on such demand models will be proportional to income elasticities [Deaton 1975]. Thus, the use of such demand models involves distorted measurement of

consumer responses and nence, the price to be paid in using such models is 'too high' [Deaton 1974]. 15 An attempt may be made to overcome these limitations by estimating demand systems that permit non-linear and non-separable preferences like the Almost Ideal Demand System [Deaton and Muellbauer 1980] 16 Such models can also be used to answer welfare related questions in a partial equilibrium framework at least for the urban sector. But the methodological problem is that the statistical properties of such models based on the NSS data are suspect. This is because the NSS estimates of total consumer expenditure at constant prices do not show any sustained growth or even substantial variation during the entire post-independence period [See, Survanarayana 19951 and hence, the scope for obtaining statistically efficient estimates of parameters of non-linear consumer preferences is limited. In addition to this limitation, some of the CGE models do not have an explicit labour market and cannot account for the dynamics of labour market changes under the various poverty alleviation programmes.17 This is not to say that these models and inferences based on them are invalid but to stress the need for appropriate modifications in their specification. Towards overcoming some of these limitations, it would be worthwhile to collect data on both consumption and productive activities of the households through integrated household surveys. Integrated surveys are important for evaluating the welfare implications of questions like increases in foodgrain prices For answering such questions, it is not enough to have information on household food consumption but data on household food production are also needed.

#### IV Summing Up

The preceding discussion emphasises the importance of data base in any discussion on poverty and identifies the major gaps for policy studies in India. Beginning with the primary question of identification of the poor based on a measure of standard of living and a minimum norm till the final stage of policy prescription, an awareness of the data base and the constraints it imposes on interpretations, etc, is quite important. The paper throws light on some such issues ignored in studies for India. It is noted that the conventional approaches to poverty identification and measurement presuppose a stationary economy. In a developing economy subject to changes in institutional parameters involving increasing commercialisation of product markets and increasing casualisation of labour markets as experienced by India in recent years, a base and concepts can yield misleading results and policy prescriptions. Therefore, there is a need for an integrated approach for a comprehensive analysis.

Available evidence on the distribution of benefits across socio-economic classes of administratively targeted poverty alleviation programmes like the IRDP shows considerable leakages to the incligible. Same holds good for public works programmes, where scope for self-targeting by fixing wages at the reservation level is considerable. Much needs to be done in the area of indicator targeting. The studies conducted by the expert group on identifying alternative indicators of poverty have their own methodological limitations and their conclusion that there is no alternative to identifying the poor except by means-test cannot be generalised for all time across the country. Same holds good for suggestions for indicator-based PDS reform by changing its commodity basket. In sum, the only effective solution seems to be decentralised approaches based on perceptions at the grass roots level.

Questions on macro strategies for poverty alleviation can be answered with appropriate computable general equilibrium models. Much needs to be done both in the specification and the estimation of such models for India: On the specification level, there is a need for agricultural household models for a predominantly rural and semimonetised agricultural economy like India. Such models cannot be estimated without appropriate integrated household surveys and without relevant data on all aspects of household economic activities, which are presently not available in India. Such studies are also important for understanding the dynamics of changes in poverty and their welfare implications.

#### **Notes**

IThis is a revised version of the paper presented at the workshop on 'Data Base for Rural Poverty Indicators' held at the National Institute for Rural Development, Hyderabad, during April 17-19, 1996]

- 1 See, for instance, the study for Cote d'Ivoire by Glewwe and Van Der gaag (1990)
- 2 The question of aggregation, i.e., how one obtains an index of poverty also matters from the point of view of policy design and implementation As the planning commission admits, one of the reasons for ineffective targeting of Integrated Rural Development Programme (IRDP) is the tendency for the administrators to focus on those who are in the neighbourhood of the poverty line so as to claim higher success, measured in terms of head-count ratios, in poverty alleviation [Government of India 1983 49].

- 3 The Seventh Five-Year Plan states: "Costeffectiveness of the programmes and immimisation of leakages should be the two guiding principles in the implementation of poverty alleviation programmes. Economic viability should be understood primarily in terms of cost effectiveness, i.e. maximum income generation per unit of total expenditure incurred. This is to be distinguished from economic viability defined as level of investment sufficient to enable a family to cross the poverty line. The ability of a poorer household to cross the poverty line depends on its overall income, i.e. income from the poverty alleviation programmes and other wage and non-wage incomes accruing to them" [GOI 1985a 51]
- 4 Glewwe and Kanaan (1989) show how household incomes can be predicted on the basis of household survey data on observable characteristics like area of residence and characteristics of household dwelling. These predictions in turn can be used to decide on budgetary allocations and income transfers to the poor so as to reduce poverty subject to the resource constraint.
- 5 see, for instance, Baker and Grosh (1994), Ravallion (1989) and Ravallion and Sen (1994) Similarly the question of alternative indicators of food and nutrition security for use in food and nutrition monitoring and evaluation systems has received considerable attention [Haddad et al. 1994]

- 6 The working group appointed by the Government of India in 1962 distinguished between private expenditure and public expenditure, the latter supposed to be incurred by the state on health, education, etc. In keeping with this distinction, the expert committee defined poverty in terms of private household consumer expenditure [Perspective Planning Division 1962]
- 7 For details regarding how the sample size, number of strata, etc, has changed over time and their implications, see Vaidyanathan (1986a)
- 8 Cited in Jose (1978)
- 9 For instance, Ahluwalia (1978) estimates poverty measures in terms of parameters of Lorenz curve, proposed by Kakwani and Pod ler (1976), of consumer expenditure distribution.
- 10 The term common property resources refers to that of the community wealth or resources over which every member of the community has equal rights for use.
- 11 These were (i) Principal occupation, (ii) Use of toilet soap. (iii) Possession of torch, (iv) Reading newspaper. (v) Lighting, (vi) Having sofa-chair, (vii) Having cot-diwan, (viii) Possession of cup-board, (ix) Possession of fan, (x) Height of door; (xi) Irrigated land per capita, (xii) Land possessed per capita, (xiii) Floor area per capita; and (xiv) Per capita income.

# Minimum Needs of Poor and Priorities Attached to Them

V Sitaramam S A Paranjpe T Krishna Kumar A P Gore J G Sastry

From an examination of the NSS data covering 1951-1991 and taking the cereal consumption deprivation as a measure of poverty the authors present an estimate of poverty in India without using the dubious concept of the poverty line. They argue that there is no need to have a poverty line to measure the degree of poverty of any community or group of vulnerable households. The method developed here reveals that cereals constitute the commodity group that occupies the top position in the hierarchy of needs, both in rural and urban areas. Next item of priority, both for rural and urban areas, is fuel and light and not clothing partly because one cannot make a 'roti' out of wheat without the cooking fuel.

If the misery of our poor be caused not by the laws of nature, but by our institutions, great is our sin

- Charles Darwin, Voyage of the Beagle

#### I Introduction

ALLEVIATION of poverty has become one of the most important items on the policy agenda of many a government, particularly in the developing countries. Economic research so far has concentrated on the issue of measuring and monitoring the extent of poverty, rather than on the issues of designing the appropriate poverty alleviation programmes. Designing such programmes requires some insights into who the poor are for whom such programmes must be designed, and what their needs are. The view of a major segment of the economics protession on these two issues has been that all those who are below the poverty line are the poor who need poverty alleviation programmes, and that their needs are based on the common perception of hierarchy of needs, such as food, clothing, shelter, health, education, etc. There are two problems associated with these economists' views. First, the idea of identifying the poor by the poverty line is neither acceptable to the policy-makers nor is it feasible, as the poor do not have a regular and stable source of income. Also it is not based on good scientific and objective reasoning. Second, there is no clear-cut empirical evidence that the hierarchy of needs corresponds to the oft-repeated slogan 'foodshelter-clothing' or 'roti-kapada-aur makan'.

These priorities may vary from community to community, and from place to place. The ordering of needs depends on the circumstances facing the people. For example, for people living in colder climates and on forest slopes, clothing and shelter may be more important than for people who live on the plains with a more favourable climate. Similarly, the food habits may vary

from place to place. Hence, what one needs is a measure of consumption deprivation that is commodity specific and community specific. The economists have, in our opinion. put undue emphasis in defining first who the poor are and then defining their poverty. It is our view that it is more meaningful and useful to define poverty as consumption deprivation, which is the opposite of welfare, and then to decide, on a case by case basis, who ought to be the beneficiaries of any poverty alleviation scheme. The choice of the beneficiaries should depend on social, economic, political, and administrative considerations. The targeting of the poverty alleviation schemes, in terms of the com modities for which subsidies are needed and the people who ought to receive those subsidies, should be region-specific. From this perspective, and given that the notion of poverty is basically relative, it is even preferable to call such schemes as welfareimproving schemes rather than poverty alleviation schemes.

The new United Front government announced its commitment to a 'Common Minimum Programme'. What the UDF and the prime minister seem to imply by this term is a minimum needs programme, as there can be a consensus (and hence the word 'common') on such minimum needs. This concept of minimum programme raises several interesting economic policy issues. It is suggestive, from the attitude of the new government, that the new government's focus has shifted from poverty alleviation to providing the minimum needs. This change in policy focus is quite consistent with the line of research we have been engaged in for the past few years on poverty measurement. We have been arguing that poverty has to be measured as commodity-specific consumption deprivation of a community, without any reference to an arbitrarily and subjectively chosen poverty line. The identification of the poor has to be based, we argue. not on a difficult to measure income, but on socially, politically, and administratively, and unambiguously determined criteria. This suggestion of ours is also quite consistent with the actual practice. It may be noted that the really poor have very irregular employment and income, and hence it is difficult to measure their incomes to check the eligibility for a poverty alleviation programme.<sup>2</sup>

This is the line of work we have been doing. In this connection we needed to identify those commodities, called necessities, in terms of which we need to assess the consumption deprivation. The identification of the most essential commodity, whose consumption saturates at the lowest income posed no problem, and it turned out to be cereals. The budget share of this commodity at the limiting income is the highest. Hence, we measured poverty through cereal consumption deprivation. But as the economy develops and the welfare of people in general improves, people move on to consume the next item on the hierarchical ladder of commodities, often by even lowering the consumption of cereals. One way of monitoring the course of economic development is to see how the consumption pattern has changed over the years in terms of bringing into consumption commodities which were on a higher rung of the ladder of commodity hierarchy. Providing to the poor only cereals at affordable prices is not enough if such cereals have to be cooked in order to consume, and if the poor have difficulty in procuring the cooking fuel. These comments suggest that there is a need to have a detailed investigation into commodity groups other than cereals that enter into the priority list of

In order to get some empirical insights into the hierarch vof needs among the households, and how this pattern has altered over years, we had examined the consumption pattern from the National Sample Survey data for various rounds, starting from the 3rd round 1991. It is the purpose of this article to share our findings with the readers and to suggest some policy implications of our findings in designing the 'minimum needs programmes' for the vulnerable sections of the household sector.

The plan of the paper is as follows. Section II presents very briefly the method we use to examine the consumption expenditure data of the NSSO employing a new form of Engel curve. In Section III we present the levels of cereal-based consumption deprivation for rural and urban India for various rounds of NSS. These are our alternate measures of poverty, based on cereal consumption deprivation. In Section IV we develop a method for determining the hierarchy of consumption needs and apply this method to the NSSO data. Finally, in Section V we present the important policy implications suggested by our method and our findings.

#### II Relation between Quantity Consumed of a Commodity and Income: Engel Curve

As income is difficult to measure, and as there are no reliable estimates of household income levels, we proxy income of a household by the total expenditure of that household. In this section we are therefore concerned about the relationship between expenditure on a specific commodity or commodity group and the total expenditure. Such a relationship is known as the Engel curve. This relationship can assume different forms. Three very commonly assumed forms are depicted in Figure. Type I relation shows that the consumption of that type of commodity increases with income but at a

Note: The V and K estimates are in rupees per capita per month (in 1960-61 prices). V and K are first estimated separately for each NSS Round. The tabulated values above are V and K adjusted for price changes between rounds.

Source. Estimated using NSSO data.

consumption of this type of commodity increases with income, but at a constant rate. Type III curve shows that the consumption of this type of commodity increases with income, but at an increasing rate.

Per cent change in the consumption of a commodity for a 1 per cent change in income is called the income elasticity of demand for that commodity. For Type I commodities the income elasticity is less than one. One very commonly used mathematical form for the Engel curves of all the three types is:

$$Log c_i = \gamma + \eta log y_i \qquad ...(2.1)$$

where  $c_1$  is the mean consumption in expenditure class 1 and  $y_1$  is the mean income in the same expenditure class. In this form the income elasticity of demand for the commodity defined above turns out to be  $\eta_1$ , which is assumed to be constant. It is quite likely that for necessities such as food, the income elasticity of demand is not only less than unity but it may also decrease with increase in income, i.e., the per cent increase in income may decrease as income increases. The above functional form cannot take care of this possibility.

It is the analogy between the equilibrium relations in kinetic models of catalysis in biochemistry and the above Type I Engel curve of economics that had provided the major impetus for our research on consumption analysis and poverty by an interdisciplinary team consisting of a biochemist, an economist, and three applied statisticians. In fact the Engel curve is an equilibrium relation between the two flow variables, expenditure on a specific commodity and the total expenditure, and hence this analogy is

models in biochemistry use a hyperbolic relation of the following type to represent the kinetic equilibrium:

$$c_i = Vy_i/\{K+y_i\}$$
 ... (2.2)

When we fitted equations (2.1) and (2.2) to the NSSO data we found that (2.2) always gave a better fit than (2.1). When we say better fit, the criteria we used to compare the two models are: (i) coefficient of determination, R<sup>2</sup>, and (ii) randomness of errors with a Gaussian distribution. It is also interesting to note that the income elasticity of demand for specification given by (2.2) does vary with income and decrease with an increase in y, a desirable property cited above.

In this study we used model (2.2) for determining the hierarchical basic minimum needs. We used the same model in our studies on poverty through consumption deprivation. Some properties of this Engel curve are worth noting, and these are given below:

(1) Dividing both the numerator and the denominator of the right hand side of (2.2) by yi we get:

$$c_1 = V/\{K/y_1 + 1\}$$
 ... (2.3)

From equation (2.3) we note that as y, tends to infinity c, tends to V. Thus, V can be interpreted as the saturation level of consumption. (V-c<sub>1</sub>)/V is the proportional shortfall in consumption from the saturation level, and it lies between 0 and 1. We had proposed that, for any community, the mean proportional shortfall of consumption of a basic necessity such as cereals from its saturation level be taken as a poverty index of that community [see Gore, Kumar, Paranjpe, Sastry, and Sitaramam 1994, 1996 and Kumar, Gore, and Sitaramam 1996].

(2) Dividing both the right and the left hand sides of (2.2) by y we get:

$$c_1/y_1 = V/\{K + y_1\}$$
 ... (2.4)

Since income and consumption move together we can assume that ci/yi tends to a constant as yi tends to zero. From equation (2.4) it follows that this limit is V/K. Thus, V/K can be interpreted as the proportion spent on the commodity, or the budget share of the commodity, at limiting (or low levels of) income.

(3) From equation (2.3) we get:

$$V/c_1 = K/y_1 + 1$$
 or  $(V-c_1)/c_1 = K/y_1 ... (2.5)$ 

From equation (2.5) it follows that  $y_i = K$  when  $c_i = V/2$ .

Thus, the parameter K may be interpreted as that level of income at which consumption is at half-saturation level. Hence, parameter K

is often called the half-saturation constant.

(4) The equilibrium quantity consumed depends directly on the forward rate constant V (need) and inversely on the backward rate constant K (cost). The proportion of income spent on a necessity(commodity) decreases with increasing income.

The hyperbolic Engel curve was fitted to the Indian data on household consumption published by the NSSO. The model was fitted using non-linear least squares method of estimation. This method requires an initial guess of the unknown parameters. Although the programme usually has certain default-values for the initial guesses, the convergence to the final estimates would be faster, and we can also be reasonably sure of a global minimisation of the error sum of squares, if the initial guesses are chosen carefully. Hence, we provided, as initial guesses estimates derived from the following linearised version of the model.

$$1/c_1 = 1/V + (K/V)(1/y_1)$$
 ... (2.6)

 $1/c_1$  was regressed on  $1/y_1$ , and the reciprocal of the intercept estimate is taken as the initial guess of V, while the ratio of the slope estimate to the intercept estimate is taken as the initial guess of K.

## Poverty without Poverty Line: Measure of Poverty Based on Cercal-Based Consumption Deprivation

The concept of poverty line has been a very controversial and subjective concept, which had placed economic research on poverty in a very shaky and vulnerable position. We had argued elsewhere [Gore, Kumar, Paranipe, Sastry, and Sitaramam 1994, 1996 and Kumar, Gore and Sitaramam 1996] that the identification of the poor can be made on the basis of commodity-specific consumption deprivation among different vulnerable groups of people, those groups having been identified by a priori criteria such as rural landless labourers, unemployed or seasonally employed persons female headed households with dependent children, etc. Our method did not require a poverty line level of income for either identifying the poor or for measuring poverty.

The beneficiaries of poverty alleviation programmes are also normally and actually chosen by criteria other than a poverty line level income. If the poor are so identified for the poverty alleviation programmes, by criteria other than poverty level income, then it makes no sense to measure their degree of poverty through a measure that depends on an arbitrarily chosen poverty line. Such a procedure of applying the traditional measure of poverty (based on a poverty line), when used to monitor the poverty alleviation

programmes, would give erroneous conclusions as the measured poverty could exclude some of the actual beneficiaries whose incomes could be above the poverty line. Hence what is needed in this connection is an insight into the commodity-specific consumption deprivation among a variety of vulnerable groups of people, identified by some policy relevant criteria. If it is desired to choose between alternate groups so as to exclude the creamy layers from the benefits of the poverty alleviation programmes one can measure the commodity-specific consumption deprivation for such alternate groups and choose, for implementing the poverty alleviation programmes, that group which has more consumption deprivation than others.

We used the NSS data for the computation of the new poverty index that does not use the poverty line. The consumer expenditure data for cereal expenditure, and total expenditures by various total expenditure classes for various NSS rounds starting from 16th round (1960-61) to the 46th round (July 1990-June 1991) were used The commodityspecific poverty indices for India for the period 1960-61 to 1990-91 were computed using the method described in Section II. Engel curves of type (2.2) were fitted separately for each year (round), and separately for rural and urban India using non-linear least squares method of estimation employing RATS computer software

The estimates of saturation consumption (V) for cereals, were deflated with the food component of consumer price index (CPI) while the estimates of K were deflated by the overall consumer price index. For rural households the CPI for agricultural labourers was used whereas for urban households a weighted average of CPI for non-manual workers and industrial workers was used along the lines suggested by Minhas et al (1987), by giving them weights of 0.625 and 0.375, respectively. This deflation was carried out to make the parameters V and K comparable over time.

There is a hierarchy of needs, the cereals being the first and most essential commodity. The estimates of V and K (adjusted for changes in food prices and overall prices), for cereal consumption are presented in Table 1. Trend lines fitted to the estimates of V and K show that there is a secular decline in both. This could imply that over time households started substituting noncereal and non-food items for cereals. This could be due to increased availability over time of non-cereal and non-food items. The estimates of V in Table 1 are almost uniformly larger for the rural data compared to the urban. The explanation given above, viz, an increase in availability of non-cereal options (in urban areas) possibly explains this pattern as well.

# Be at 60 what you are at 30. Self-dependent.

#### Highlights

- A unique pension plan for self-employed, professionals and salaried class.
- Offers attractive lifelong guaranteed pension benefits coupled with Family Pension.
- Option to commute 25% of the Corpus totally tax-free.
- Life Cover for Family Pension.
- · Female lives are also eligible for Life Cover.
- Further improvement in guaranteed pension benefit likely.
- Full tax exemption on premium upto Rs.10,000/- every year under 80 CCC(I).

For more details, contact your nearest LIC office or your agent today.

As mentioned earlier (refer to equation (2.4) and the comment below that equation) the proportion of expenditure on the specific commodity (cereals) turns out to be V/(K+y) and this becomes V/K as income tends to zero. Thus V/K is the limiting proportion of expenditure on cereals. Table 2 presents estimates of V/K for cereals.

An interesting aspect to note is that this V/K ratio for cereals or "proportion spent on cereals at limiting income" has been higher in the urban India up to 1970 than in rural India. But from 1970 onwards (except for 1972-73) this proportion is less in urban India than in rural India. This seems to be partly due to the green revolution. This may also be partly due to the PDS being more urban-oriented as V/K showed a declining secular trend in urban area only. The overall constancy of V/K for cereal consumption in rural India also justifies using cereal consumption deprivation for measuring poverty, as most of the commonly understood poor (agricultural labourers and marginal farmers) live in rural areas and the proportion of total expenditure that they spend on cereal consumption expenditure is very high being 0.75 on an average and stable.

Table 3 presents the poverty indices based on the cereal-based consumption deprivation.<sup>3</sup> The poverty estimates of Table 3 show a time trend in this poverty index. The cerealbased poverty index clearly demonstrates that there is a higher incidence of poverty in rural India and that the difference between rural and urban poverty has reduced between 1960-61 and 1990-91. It must be mentioned that the urban and rural poverty indices given here are based on different saturation norms (Vs). Hence we cannot strictly compare the rural and urban poverty indices. The maximum cereal consumption differs between rural and urban areas, partly because the commodity spectra available are different in rural and urban areas. We can, however, talk about the rate of decrease in poverty between urban and rural poverty and note that this decrease is much more in rural areas than in urban areas.

The poverty index presented here is based on deprivation from saturation norm that is specific to each data set. Since this saturation norm (i e, estimated V) is different for each year as well as for urban and rural samples, comparison of the poverty indices needs a careful explanation. If our concern is about consumers' feeling of consumption deprivations from their own saturation point (this may be termed 'felt-deprivation' derived from the concept of felt need) then the comparisons of above indices are alright. Our measure of poverty is a relative measure relative to the maximum expenditure on cereals, which differs between rural and urban areas. While we may, under certain circumstances, be

Note: For some rounds when V/K estimate is outside the plausible range they are omitted.

justified in making temporal comparisons within rural and urban areas separately, it is not quite proper to make comparisons between urban and rural poverty indices.<sup>4</sup>

To shed more light on this problem we deflated the expenditure data of each NSS Round with the appropriate price index and examined to see if there is a long-run stable Engel curve that fits the data with a single V that can be used in computing the poverty index for each round. It was felt that urban and rural consumption patterns are not comparable anyway. Hence two separate long-run Engel curves were estimated, one for the rural areas and another for the urban areas.

Table 4 presents the poverty indices based on the assumption that there is a common Engel curve for all the rounds of NSS after adjusting the data for price level changes from year to year. These estimates seem to suggest that rural poverty had increased in India from 1960-61 to 1967-68 and then recorded a secular decline until 1989-90. There is again a sharp increase in rural poverty in 1990-91. An examination of urban poverty indices of Table 4 suggests that the urban poverty more or less remained stable until 1967-68 and then registered a slight decline and thereafter remained stable until 1989-90. Likerural poverty urban poverty also registered a sharp increase in 1990-91.

## IV Prioritisation of Household Needs

When the above Engel curve was fitted to the various groups of commodities for which NSSO presents its expenditures we observed that only for some of them, particularly cereals, the fit was good. In some cases Type II and Type III curves of the Figure scemed more appropriate. If the Engel curve for cereals has a Type I shape it follows that the expenditure on a commodity group consisting of all other commodities should have an Engel curve of Type III. Noting that the expenditure on cereals forms a major portion of total expenditure by a household we felt that the slope of the curve in some cases could be imperceptible if the curve is drawn against total expenditure, and that it may be perceptible if it is plotted against budget available after deducting the expenditure on cereals. This in fact turned out to be the case.

The above observation suggested that there could be a hierarchy of household needs among the poor, the intensity of need being the greatest for cereals. Once the cereals need is fulfilled the household may spend a part of the remaining income on a commodity, expenditure on which saturates next. Having met the expenditures on the two most important items the household may move on to spend on the third item, from the remaining income, and so on.

We tested this model of needs-hierarchy using the NSSO data from 1951-1991, viz, from the third round to the 45th round. After fitting the Engel curve of model (2.2) for cereals we asked the question which of the remaining groups of items takes the second position in terms of saturating next, with the best fitting hyperbolic relation plotted against the remaining part of the total expenditure. Having thus chosen the second most needed item, separately for each round and separately for rural and urban samples, we asked the question likewise — what item, out of the remaining items, would qualify to take the third position, and so on.

Our findings are reported in Tables 5A, 5B, and 6. In Tables 5A and 5B we present the sequence in which commodity groups appear along with their budget shares at limiting income (V/K values). In Table 6 we present the frequency with which a commodity is selected (out of a total of 29 rounds) as one of the top five priority items. From these results it appears that next to cereals comes the category 'fuel and light', the major component of that being possibly the cooking fuel. After fuel and light comes 'edible oil. After dible oil comes 'meat, egg, and fish' in rural areas and 'sugar' in urban areas.

The parameters 'V' and 'K' estimated at each stage refer to the situation where the independent variable of the non-linear Engel curve is the 'remaining total expenditure', after the expenditures on commodities of earlier stages are subtracted from the total expenditure. The V/K at each stage needs to be adjusted to express expenditure on that commodity as proportion of the total

expenditure at the limiting income. The adjusted V/K are presented in the parentheses in Tables 5A and 5B From these adjusted V/K figures it becomes quite clear that fuel and light occupies a high position next to cereals in terms of budget share at limiting incomes.

#### V Policy Implications of Our Results

It is our view that as a part of its common minimum programme the present UDF government must design programmes aimed at improving the welfare of the vulnerable sections of the community (households). Such programmes must not be looked upon as poverty alleviation programmes of the traditional variety with questionable, dubious and outdated methods of defining and measuring poverty. Instead, we propose that a new thrust be given to poverty alleviation through minimum needs programmes. In designing these programmes the vulnerable groups may be chosen from a set of alternative groups through criteria other than the poverty line, criteria based on social, political, and administrative considerations aided by our measure of consumption deprivation. What we mean by this is that among a set of alternate groups chosen a priori according to sociological, economic, political and administrative criteria one group may be chosen as the beneficiary group for the government's programme on the basis of the criterion of having the highest level of commodityspecific consumption deprivation

From the findings reported in the previous section on the hierarchy of needs it becomes quite apparent that after cereals the next most important commodity group is fuel and light, which includes cooking fuel. After these two comes the group edible oils. In view of these results it can be suggested that in revamping the PDS the new government should omit the creamy layer from the PDS beneficiary list and spend more on providing cooking

TABLE 6 FREQUENCY WITH WHICH A COMMODITY
WAS SELECTED IN FIRST FOUR PRIORITY ITEMS
ACCORDING TO ADJUSTED V/K

| ltems               | Rural | Urban |

| Salt                | 0     | i     |

through PDS.

We also feel that more detailed analysis needs to be done along the lines proposed here to assess the commodity-specific consumption deprivation among different vulnerable groups in order to design proper welfare-improving government programmes based on the minimum needs approach. The poverty line and the traditional poverty measures based on the poverty line can be dispensed with altogether.

While fuel and light have been clubbed together in this analysis of NSSO data there are other studies that have examined the role of cooking fuel (fuel wood, charcoal and kerosene) in household consumption. In particular we may refer to the work of Reddy and Reddy (1985) that examined cooking fuel consumption by a sample of households in Bangalore city. A similar survey of cooking fuel consumption in rural North India was undertaken by NCAER (1978). The study of Reddy and Reddy clearly shows the importance of consumption of cooking fuel among low-income households even in highly urbanised areas such as Bangalore. The long lines of the urban poor to get kerosene is a pathetic sight we confront today, even after the government permitted the import and sale of kerosene by private parties. One strong implication of our study is to highlight the importance of cooking fuel for the poor households

Another major policy implication of our study is that in the currently prevailing attitude of giving primacy to local bodies in designing and monitoring the poverty alleviation programmes the targeting of the programmes in terms of the choice of the beneficiaries and the choice of commodities must be specific to each local community. Our research emphasises this point and also provides a method of choosing these targets for each local community.

Although we used the NSS data and presented our results for the country as a whole we emphasise that this sort of exercise has to be done at disaggregated levels, possibly at the district, taluk, and village or (urban) block levels. The NSS type of data which has very few observations at such levels of disaggregation are not suitable for this purpose. We hope our study will drive home the need to generate data bases at grass roots level to design and monitor social welfare programmes. We also hope that the various NGOs whih are actively engaged in ocial welfare schemes all over the country will come together to develop standardised tata bases at the village and block levels.

In short, we hope that this study of ours all convince both the researchers and the labey makers that the concept of poverty have can be dispensed with. We also hope that our study will form the beginning of

worthwrite social science policy research through research studies on consumption deprivation at the village and block levels.

#### Notes

[This work is based on an ongoing research by these authors on measurement of poverty without using a poverty line. The authors' new method for measuring poverty is based on commodityspecific consumption deprivation, the commodities chosen being the most essential basic needs. This is a radically different method, compared to the highly discredited traditional methods that employ a questionable and subjective poverty line. The interested reader may refer to Gore, Kumar, Paranjpe, Sastry, and Sitaramam (1994 and 1996) and Kumar, Gore and Sitaramam (1996) This research was initiated by V Sitaramam at the National Institute of Nutrition several years ago in collaboration with J G Sastry. It is now being continued by Sitaramam, during the last two and a half years, in association with Gore, Krishna Kumar and Paranjpe The authors thank S Subramanian and Vinod Vyasulu for their comments on an earlier draft of this paper Krishna Kumar thanks Sushant Mallick, G Nagaraju, and N S Manjula for their research assistance.]

- 1 It is our view that an attention to semantics and linguistics is quite useful here. The economists' focus so far has been on the 'focus axiom' that requires the noun 'poverty' to be associated with the substantivised adjective 'poor', or the associated noun 'the poor'. The English language, however, gives the nown 'poverty' a position that does not necessarily depend on the identification of 'the poor'. In other words the English language does not say that poverty is only what 'the poor' possess. The Webster's New Collegiate Dictionary gives three different meanings to the word poverty (1) the state of one who lacks a usual or socially acceptable amount of money or material possessious, (2) scarcity or dearth, (3) debility due to malnutrition. The second meaning refers to deprivation and that is what we wish to emphasise
- 2 It is trivial that there should be a direct relation between unemployment and poverty. This relationship is vividly brought out in terms of published official statistics for urban areas in selected Indian States by Vyasulu and Vani (1996).
- 3 We have shown in another paper that the poverty index we propose satisfies all the major axioms that such an index should satisfy (axioms such as those proposed by Sen (1976), and Kakwam (1980)) except the focus axiom. We argued that there is no need to have the focus axiom if we define poverty first without defining who the poor are Isee Gore, Kumar, Paranjpe, Sastry, and Sitaramam 1994 and 1996. The proofs that the poverty index satisfies all the major axioms were based on the observation that the index is the mean of deprivation, which is expressed as a function of income, the mean being taken with respect to the income distribution [Kumar 1993].
- 4 The problem here is quite similar to the problem of real income comparisons posed by Samuelson One can make Scitovsky type of comparisons between rural and urban poverty measures by substituting urban saturation levels

of consumption for rural households and rural saturation levels for urban households, and then comparing them as transferable public expenditure equivalents

## **Economic Reform and Rate of Saving**

#### **EPW** Research Foundation

The latest CSO data show an improvement in domestic saving and investment in 1993-94 and 1994-95, but an examination of the sources of that improvement and the later sharp reduction in the financial saving of the household sector during 1995-96, despite two years of accelerated GDP growth and high interest rates, as brought out by the Reserve Bank of India's latest estimates, suggests that no clear upward trend in saving and capital formation has emerged yet.

Against this background, this paper discusses some issues relating to the measurement of domestic saving and capital formation. Further, it contends that the evolving economic structure and policy framework are such that the Indian economy is unlikely to achieve the kind of rapid increases in domestic saving which propelled the remarkable growth of the east and south-east Asian countries.

#### I The Issues

PREMACHANDRA ATHUKORALA and Kunal Sen (1995) question the basic thrust of our paper [EPWRF 1995] which was that not only have there been persistent declines in overall domestic saving and capital formation ratios since 1990-91 as brought out by the CSO's official series, but also that the existing estimation procedures may have introduced some upward bias in the measurement of household financial savings, and in turn, in that of overall domestic saving, particularly for 1993-94. Subsequent to the appearance of their critique, saving and investment data have been published by the CSO for one more year, namely, 1994-95 and the estimates for 1993-94 have been revised. Besides, the Reserve Bank of India (RBI) has just released its estimates of household financial savings for 1995-96 [RBI 1996]. The CSO data show an improvement in the domestic saving and investment scenario during 1993-94 and 1994-95 (Tables 1 and 2), but a review of the sources of that improvement and the subsequent drastic reduction in the saving of the household sector in financial assets during 1995-96 as per the RBI's latest estimates, despite two years of accelerated GDP growth and high levels of interest rates for saving instruments, suggests that a firm upward trend in saving and capital formation ratios has not yet set in. We thus see no ground to alter our basic perspectives as articulated in our original paper, but the primary purpose of this note is essentially to respond to the substantive questions raised by Athukorala and Sen (A-S henceforth) on the measurement of domestic saving and capital formation and the economic fundamentals which purportedly underscore their perception of the given saving behaviour.

The measurement issues which A-S raise essentially concern two specific areas. I arst, they note that the fall in the domestic saving rate since 1990-91 has been driven by the decline in household physical saving which, they emphasise, is a "statistical

artefact" arising from possible measurement errors in the estimation of gross domestic capital formation (GDCF). Their second critical comment relates to our hypothesis that the only silver lining in the otherwise depressing saving scenario in the form of an improvement in household financial saving during the three-year period 1991-92 to 1993-94 may have arisen from a possible upward bias introduced in the existing method of estimation. A-S contend that they failed to find any convincing evidence regarding such overestimation of household financial savings.

The following two sections deal with the above substantive issues. In responding to the questions raised by A-S, some clarifications on the methodological issues are found necessary as the interpretations offered by them are apt to give misleading impressions. Thus, while dealing with the questions relating to the possible under-estimation of household physical assets formation (in Section II), clarifications are offered on the alleged underreporting of production and incomes and its implication for the estimation of capital formation (and saving) to GDP ratios.

Similarly, while addressing the issue concerning possible overestimation of household financial saving (in Section III), it is clarified that household saving in such short-term monetary assets as currency and bank deposits derived through the 'residual' method does not imply that the balance of such financial asset accruals necessarily form any constituent parts of the savings of the private corporate and public sectors. In the final section (Section IV), a brief comment is offered on the tenability of saving and investment trends in recent years and how they fare in relation to the perspectives which we brought to bear, in our earlier paper, on the disappointing performance in the first three years of reform.

#### U Decline in Household Physical Savings

The gravamen of A-S's critique of our paper is their assertion that "the apparent

decline in the household investment in physical capital (and hence household saving rate)... has largely, if not entirely, emanated from an underestimation of GDCF in recent years" (p 2187). While they concede that this issue can be meaningfully resolved only through a careful study of the estimation procedure adopted by the CSO and the possible inconsistencies between the procedures used and changing patterns of 'production relations in the economy', for which however ready information is not available, the authors put forth two explanations for their hypothesis of a systematic downward bias in the measurement of GDCF since 1991, namely, first, the ongoing process of informalisation of the Indian industry which would have been intensified following policy reforms in 1991, and second, the rapid growth of capital (and intermediate) goods imports, both of which are not being adequately captured in the commodity flow method. The first factor relates to the phenomenon of under-reporting of production, in particular, failure "to capture construction material, machinery and other investment goods produced in the unorganised sector" (p 2188) and the second, the lags in the compilation of trade data and the use of historical ratios of imported to total available capital goods. Hence, the CSO results, according to A-S, may be tending to understate domestic capital formation.

#### IMPACT OF UNDER-REPORTING

In this respect, it is necessary to be clear about the general implications of underreported and unreported production on the estimation of capital formation (and saving) and also on the ratios of capital formation (and saving) to GDP. It is generally perceived, as the Raj Working Group [RBI 1982:41-42] opined, that the extent of under-reporting would be relatively more in total GDP than that in capital formation or saving: "All that can therefore be said is that there is prima facie reason to suspect underestimation of GDP and that – though it is impossible even to guess on the basis of presently available knowledge how large a difference it could

make to the aggregate - any allowance made for it would tend to lower somewhat the estimated ratios of investment and saving in the economy" [RBI 1982: 42]. This is obviously so because hoarded currency and unreported holdings of other financial assets at the level of individuals or other entities are nonetheless captured in aggregate financial flows, which are generally independently derived from the financial accounts of the financial sector institutions.1 Gold and consumer durable goods holdings, hidden or otherwise, do not constitute any part of capital formation or saving estimates. Unrecorded and unreported physical investment based on independently estimated supplies of cement, steel and other key construction materials and machinery and equipment produced in the registered sector are all captured in the commodity flow method. By far the weakest links in the estimation edifice are the labour-intensive construction works and the contribution of unregistered manufacturing to the supplies of 'machinery and equipment' through historical ratios. The phenomenon of unreported output is widely acknowledged as a universal one, in registered as well as in unregistered and unorganised sectors. But, considering the data sources and compilation procedures, it seems quite reasonable to accept the hypothesis that unreported or uncaptured proportion would be relatively more in total GDP than in domestic savings and capital formation; this should also be true for major individual sectors.2

The commodity flow method came in for detailed scrutiny at the hands of the Raj Working Group. Conceding that there are several points at which errors and biases may enter, the Working Group argues that where the 'commodity flow' method is used, the estimates of construction materials and machinery produced in the 'unorganised sector', of construction inputs other than the five basic ones, and of factor income payments (based on proportions derived from field data for remote years), are all evident sources of error; the basis of estimation of labour-intensive construction appears to be still more tenuous. The Group, however, argued that, "While this is obvious, there is no way of judging the precise extent of the errors involved" [RBI 1982:14]. Furthermore, it was recognised that there was no merit in believing, contrary to what A-S think, that estimates of capital formation and saving for the public sector and the private corporate sector were any the better.3 Hence, any upward or downward bias in the form of fixed assets formation in these organised sectors (through inflated project costs, leakages of various kinds or mere estimational errors) would have a corresponding downward or upward bias in the estimates of assets formation in the household sector.

With all these possible errors, however, there are checks and balances within the comprehensively designed estimation procedure which finally produces as reasonable a set of estimates as is possible given the structure of the economy and the inherent problems in generating reliable data. Hence the size of errors cannot be such as to falsify the underlying trends revealed in the CSO series. "It is doubtful whether the estimates for any other country at a similar stage of development have a much firmer foundation" [RBI 1982:49]. To buttress their considered judgment, the Raj Working Group also quote the situation in this respect that obtained in the US as late as towards the middle of the 1950s.4

One must hasten to add that it was not as though that there was no scope for further improvements in sources and methods of estimation adopted by the CSO in India. Many historical field survey results are required to be updated rather drastically and with greater frequency, which in effect is the only method of improving the data base. A series of suggestions were made by the Raj Working Group towards that end and the CSO have been making use of them on an ongoing and continual basis from year-toyear, based on fresh results thrown up by various periodic field surveys ICSO 1988. Gothoskar 1988 and Subba Rao 1993 and 1994] which is what is conferring on them a status of general acceptance.5 In the circumstances, unless we can identify concrete sources of underestimation or overestimation arising from the commodity flow method and provide alternative sources of data and methods of compilation or unless obvious and distinct contradictions are noticed between the saving and capital formation estimates on the one hand, and economic fundamentals on the other, the Raj Working Group judgement that there was no way of pinpointing the precise extent and direction of the errors involved, still holds good. The only one example cited by the A-S paper of the phenomenon of informalisation of the Indian industry as possibly contributing to an underestimation of GDCF is in fact a questionable proposition, as we presently attempt to show.

#### INDEPENDENT EVIDENCES

Before we deal with the issues of informalisation of industry and lags in external trade data as the possible contributory factors for the alleged downward bias in the measurement of GDCF, we wish to bring out certain specific indications which corroborate with the observed decline in GDCF.

First, it is necessary to bear in mind that the Indian economy has been facing major stabilisation and structural adjustment programmes since 1991-92 and that a decline in capital formation ratio should be an obvious concomitant. How much could have been the decline and which sectors faced this decline, are questions that need to be addressed. In this context, at the aggregative

If you're looking at maximum business advantage in terms of payload, plus all the benefits of an LCV, then the Ashok Leyland Cargo 709 is it.

#### HIGHEST GVW AND **PAYLOAD**

all LCVs.

strong ladder-type frame. Its deep side members. Look at the heavy duty axles. The 709 is sturdier : by design. It is rated for 7.35 T GVW and 3.95 T Payload the highest among

## **FULL-AIR BRAKES**

It's nice to know that when you're cruising at high speeds and need to come to a sudden stop, the Cargo's dual line full-air brakes won't let you down. What's more, Take a look at the Cargo's : its self-adjusting mechanism makes it virtually maintenance free.

When you sink into the adjustable seats of the Cargo, feel the space around you and reach out for the ergonomically designed controls, you'll realise what a fatigue-free driver means to road safety.

Add to all this, features like tilt cab for easy maintenance, competitive pricing with finance support, easily available indigenous spares, a country-

weight champion among LCVs today.

wide service back up... You'll agree the Ashok Leyland Cargo 709 is the undisputed heavy

Cargo 709.

The heavy weight champion among LCVs.

Also available in the Cargo Series 9 tonne GVV trucks, to be followed by 13 and 16 tonne GVV trucks

level, one of the concrete experiences has been that the estimated foreign capital inflows to GDP ratio fell by over three percentage points between 1990-91 and 1993-94, the obverse of a sharp compression of current account deficit on the balance of payments (except for minor compositional differences). Secondly, a substantial part of the fall in GDCF – about one-half – is accounted for by the decline in 'change of stocks', which has, as we explain below, significant corroborative evidence based on microeconomic and sectoral trends.

#### REDUCTION IN FOREIGN INFLOWS

The medium-term stabilisation programme in 1990-91 and 1991-92 began with drastic measures of import controls supported by highly restrictive credit policy (RBI 1992:6). This was followed by significant slowdown in the growth of developmental expenditure by the central government, from an annual compound rate of 12.2 per cent during 1985-86 to 1990-91 to 7.3 per cent during 1990-91 to 1993-94 [RBI 1995:149], the latter being much less than the average inflation rate of 10.7 per cent per annum during the same period; the average inflation rate in the previous five-year period was 7.8 per cent per annum. As percentage of GDP, the centre's developmental expenditure fell from 11 per cent in 1990-91 to a 9.2 per cent

in 1993-94. Even the growth of the states' development expenditure decelerated during this period. These measures resulted in an unprecedented level of import compression which began in 1991-92, with the level of merchandise imports in US dollar terms even in 1993-94 at \$ 23,985 million being much less than that of 1990-91 (\$ 27,914 million) (BoP data). As a result, the current account deficit and consequently, foreign capital inflows slumped to 0.3 per cent of GDP in contrast to a level of 3.4 per cent in 1990-91 - a fall of over 3 percentage points (Table 2). This comparison with 1990-91 may appear incorrect as that year faced a crisis on the external economic front, but even a comparison of the annual averages for the preceding and succeeding three years reveals a fall of over 2 percentages points in the ratios of capital inflows.6 Thus, the dramatic fall in foreign capital inflows, which go to finance domestic investment. would have contributed to a corresponding decline in the GDCF to GDP ratio between 1990-91 and 1993-94, unless it could be proved that there was a simultaneous rise in the domestic savings ratio, which we rule out.

#### DECLINE IN INVENTORY BUILD-UP

Another independent evidence of a sizeable decline in the ratio of GDCF is found in the behaviour of 'change in stocks';

the latter fell by 2.1 percentage points between 1990-91 and 1993-94 (Table 3). Measurement of inventory build-up is based on data marshalled by the CSO from diverse sources, and evidently there can be errors in estimation. But, in regard to the above reduction in the ratio of 'change in stocks' to GDP, there is significant direct or corroborative evidence in micro-economic or sectoral data. Inventories generally behave contra-cyclically [Sen 1964]. In the Indian case the structural features also play a role. The year 1990-91 had preceded with high growth both in agriculture and manufacturing alike but the macro-economic crisis, particularly that originating in the external sector, was looming large on the horizon. Thus, on account of comfortable supplies, the stock build-up became large. By the time the Indian economy reached 1993-94, the scope for further build-up of agricultural commodities was limited. As for the manufacturing sector, the unusually low level of industrial growth persisting during the three-year period (0.6 per cent, 2.3 per cent and 6.0 per cent, respectively, as against 8.5 per cent per annum during the decade of the 1980s) left little room for any sizeable stock build-up by 1993-94.

Coming to concrete evidences on the above phenomenon, first, independent studies on the finances of the private corporate sector

provide some indications for the fall in the growth of 'change in stocks'. Table 4 presents data from three sets of company finance studies, which uniformly bring out the drastic decline in stock build-up by the private corporate sector from about 20-22 per cent growth in 1990-91 to a growth of 5-8 per cent in 1993-94. Evidently, the inventory growth of 20-22 per cent during 1990-91 was normal with inventories to sales ratio recording only a fractional rise [RBI 1993], whereas in 1993-94 there was "heavy offloading of inventories" in many industry groups [ICICI 1995]. The CSO data suggest depletion of inventories during 1993-94 with the "change in stocks" of the private corporate sector being negative at (-)0.4 per cent of GDP as against a positive 0.8 per cent during 1990-91 (Table 3). Assuming that the RBI sample of the private corporate sector is much larger and relatively more representative, the data released by the CSO on the private corporate sector cannot be by and large disputed.

Interestingly, such distinct fluctuations in the rate of inventory build-up were also noticed in the early 1980s as well as the mid-1980s (Table 3) for which there is again confirmatory evidence in corporate sector data (Table 4) or in distinct agricultural trends (GOI 1996). In sum, there is sufficient supportive evidence in the behaviour of foreign capital inflow and 'changes in stocks', justifying the fall in GDCF during 1990-91 to 1993-94. We now revert to the themes of informalisation of industry and lags in trade data addressed by A S.

#### LAGS IN TRADE DATA

Analysing the simpler question of lags in foreign trade data to begin with, we do not find the factual basis for charging the system with lags in trade data giving rise to incorrect application of historical ratios of imported goods to total capital goods available for investment. It is true that imports of capital goods have been rising at a rapid pace during the post-reform period. Between 1990-91 and 1993-94, the quantum index of imports of machinery and transport equipment (base: 1978-79=100) rose from 441 in 1990-91 to 715 in 1993-94 suggesting a compound growth rate of 17.5 per cent per annum as against a compound growth of 9.7 per cent per annum during the preceding quenquennium 1985-86 to 1990-91. What is more, during the same period, the growth in the quantum index of exports of machinery and transport-equipment decelerated rather drastically from 19 per cent per annum to 4.8 per cent per annum. Thus, there is no gainsaying that the proportion of net imports in total availabilities of capital goods (including metallic and non-metallic mineral products) would have risen during the postreform period.

Even so, there are two considerations which go to question the relevance of lags in external trade data for the thesis of systematic underestimation of GDCF. First, as the data quoted by A-S themselves suggest, insofar as the compilation of National Accounts Statistics (NAS) are concerned, there was no lag in the availability of foreign trade statistics. The CSO's Monthly Abstract of Statistics for October 1994, released in December 1994, had quoted the commoditywise import figures for the full fiscal year 1993-94 and that is precisely the latest year for which the NAS would have been under compilation around that period (The 'quick' estimates for 1993-94 were released in February 1995). This year the DGCI&S's monthly publication Foreign Trade Statistics of India (principal commodities and countries), covering the full financial year statistics for 1994-95, was already in the public domain in June 1995, that is, more than six months before the CSO would begin tabulating the NAS for that year. What is more, these data are available to public agencies like the Planning Commission, the RBI and the CSO in a specially-documented form sufficiently in advance; this has been so now for some years. This is enough of an evidence to question that lags in external trade data may have given rise to an underestimation of the rise in aggregate capital formation.

Secondly, even if hypothetically there was a lag in export-import data, the relatively low level of net imports of capital goods (including metals) in relation to total domestic capital formation and more importantly, as proportion of GDP, leaves less scope for any noticeable underestimation in the GDCF to

GDP ratio on that count. For example, the actual net imports of such capital goods (including metals) aggregated about Rs. 11,200 crore during 1993-94, which constituted only less than 7 per cent of GFCF.

#### GROWTH OF INFORMAL SECTOR

In respect of the substantive theme put forth by A-S, we wish to argue that the possibility of an underestimation bias in aggregate GDCF originating in the failure of the commodity flow method to capture the fast growth of the informal sector during the post-reform period, appears to us to have been exaggerated, and in fact, untenable on many considerations. We question the empirical basis of the thesis of non-reporting of investment goods production in the smallscale sector to the neglect of the phenomenon of the possible non-reporting of the production of all goods and services in this sector. A-S argue that the reported decline in the household capital formation was spurious because the total GDCF waunderestimated. Secondly, total GDCF was underestimated because the relative performance of small-scale units in recent years as compared with that of the private corporate sector was not captured in the CSO's estimation procedure. The process of 'informalisation' of the Indian industry must have got reinforced since 1991 because the incentive structures and the institutional setting created by the new policy regime seem to have 'tavoured the profitable operation of small-scale units in the manufacturing sector; consistent with this small-scale bias in the policy regime, most industries in the consumer goods sector have in fact performed better than the average for

the manufacturing sector (A-S base this on the CSO's index of industrial production).

Before we delve into the 'informalisation' question, it is necessary to point out a few factual inaccuracies in the A-S formulation. First, they have bracketed the 'household' sector with "unincorporated firms and household production units in manufacturing", which is obviously incorrect. As per the CSO's estimation, gross capital formation of the private sector in unregistered manufacturing, constituted only about 18-20 per cent of total household investment in the recent period. A part of the registered manufacturing may also belong to the category of unincorporated units.7 Even so, more than three-fourths of household investment is occurring in other sectors: agriculture (about 29 per cent), real estate, ownership of dwellings and business services (39 per cent) and private transport, etc (15 per cent). As proportions of household investment, some of these ratios for sectors other than manufacturing may be somewhat lower as the investment figures used here are inclusive of private corporate sector investment. In this regard, a special tabulation undertaken by the RBI suggests that of the total GCF by industry of use for the period 1980-81 to 1988-89, the share of unorganised manufacturing was only about 11 per cent of the GCF attributable to all the unorganised sectors together throughout the period, the balance being attributed to non-manufacturing unorganised sectors [RBI 1993c:17-19]. In the circumstances, it is improper to base the above hypothesis on the so-called incentive structure shifting the balance of activities in favour of the informal sector in manufacturing alone.

To the point, data presented in Tables 5 and 6 give a synoptic view of the industrywise composition of gross capital formation and gross fixed assets formation, respectively. As per data generated by the CSO on gross capital formation by industry of use, of the 3.2 percentage points fall in the aggregate GDCF to GDP ratio between 1990-91 and 1993-94, 1.3 percentage points are attributed to the manufacturing sector: 1.1 points in registered manufacturing and 0.2 points under unregistered manufacturing (Table 5). The balance 60 per cent of the decline in GDCF by industry of use has occurred in various other sectors: agriculture, transport (other than railways) and real estate. The decline, though of a smaller magnitude, has been equally widespread in gross fixed assets formation, but it has been more conspicuous in sectors other than manufacturing (Table 6).

The second factual inaccuracy in the above formulation relates to the CSO data on index of industrial production cited by A-S, wherein they state that "most industries in the

consumer goods sector have in fact performed better than the average for the manufacturing sector, in particular the year 1993-94" (p 2186). There are three aspects of these data which tend to question the factual basis of the inference drawn by them from the above statement.

(i) First, the data cited by them relate to the CSO's index of industrial production with base 1980-81=100 which essentially covers items produced by the medium- and large-scale units except for textiles in the decentralised sector and 18 items out of 836 reserved for the small-scale industries (SSI) sector. These 18 reserved items constitute a minuscule group with a weight of 8.44 per cent of the total weight of the manufacturing sector and are scattered over all 17 major industrial categories for which the CSO puts out two-digit level production indices and which A-S quote. In the food processing industries group, for instance, the only reserved item covered is that of 'biscuits', under 'paper and paper products', wrapping paper, and under 'leather and leather products', indigenous type of footwear.

(ii) Secondly, the trends in the index of industrial production have been used by them in a partial and selective manner. As depicted in Table 7, consumer goods industries as a group have not at all shown any annual growth higher than that of the

Source CSO, Quick Estimates of Index of Industrial Production (Monthly Press Releases).

manufacturing index during the three-year peiod 1991-92 to 1993-94 which is under critical scrutiny - not even in 1993-94 when the manufacturing index grew by 6.1 per cent and the consumer goods group by 3.9 per cent. Even the latter growth was due to a phenomenal expansion in consumer durables in 1993-94 (16.3 per cent), while the consumer non-durables group (which embraces all two-digit level items cited by A-S) grew just by 1.3 per cent. What is more, almost all of those two-digit level items supposedly dominated by production in the SSI grew at a faster rate before reforms; for instance, they grew by about 9 to 12.5 per cent each in 1990-91 when the manufacturing output as a group grew only by 9.0 per cent.

(iii) Thirdly, we have made a special tabulation of the output figures broadly for 18 SSI reserved items which are included in the CSO's general index (see Table 8). We then find that an overwhelming number of items in them in fact experienced very niggardly growth; eleven out of 18 items experienced growth ranging from -21 per cent to 4 per cent during 1993-94 when the manufacturing sector as a whole grew by 5.5 per cent. We note that in respect of many items the CSO data are inclusive of production generated by the large-scale sector but as these are reserved items, SSI's growth should theoretically set the trend for these items. Even amongst the capital goods items on this list, there is a mixed picture. But interestingly, a pre-budget survey undertaken by the Confederation of Indian Industry (CII) in early 1994, covering its 70 small industry members having significant links to the capital goods sector and comprising manufacturers of machinery, machine tools, electrical machinery, appliances, apparatus and parts, metal products, transport equipment and parts, and basic metals and alloy industries, summed up the results thus: "The small-scale units in the capital goods sector are suffering greatly owning to poor offtake from larger units and a staggering in deliveries taken by customers" (The Observer of Business and Politics, February 17, 1994).

Thus, the data on indices of industrial production cited by A-S provide no basis

to believe that SSIs grew at a faster rate than the medium- and large-scale industries during the period 1991-92 to 1993-94, or even in 1993-94 alone.

While on the subject of factual inaccuracies, we should also not lose sight of the fact that the whole debate on the SSI sector raised by the A-S paper concerns the possible inability of the CSO to capture, in its capital formation estimates, the use of construction material, machinery and other investment goods produced in the unorganised sector. The growth of consumer goods units in the informal sector is hardly relevant for this debate except for the secondary demand they may generate for investment goods. If under-reporting of total output is the question, both GDP and investment components get under-reported and the possibility is that investment to GDP ratio will not improve on that count, as has been explained earlier.

#### GROUND REALITY AGAINST INFORMAL SECTOR

It is our contention that while various promotional and protective measures for assisting the small-scale and informal sector growth have been formally continued even under the structural adjustment programme, the ground reality regarding the incentive structure, the institutional setting and the bargaining dynamics in the post-reform period has decidedly tilted the balance of advantages in favour of the medium- and large-scale industries in the private sector and against the small-scale and informal enterprises. While direct statistics on the actual performance of informal sector in

regard to output and investment trends in the post-reform period are indeed hard to come by (and hence this dispute and debate), we are convinced of the above proposition based as it is on a detailed review of the corroborative indicators for the first three years of reforms.

In the first place, it is not so much the positive incentives like 'reservation' for the SSIs which provide an impetus to their growth as the negative protection in the form of a high differential in excise duties as between the small-scale and large-scale industries that encouraged the former's growth. Also, the importance of 'reservation' for the SSI units is considerably exaggerated. The second all-India census of small-scale industries (1987-88) showed that the share of output of 843 items in the total production of 1,075 products reserved for exclusive production by SSIs was about 28 per cent (except for multi-product manufacturing units producing reserved items beyond the fourth leading item, 1 e, fifth in descending order and onwards) [Development Commissioner 1992:110]. Similarly, only 48 reserved items figured amongst the 200 leading products (reserved and unreserved items) in the SSI sector each with production worth over Rs 40 crore and the output of those 48 products constituted 36.1 per cent of the total production of the leading products [Development Commissioner: 110 and Ramaswamy 1994]. About 80 per cent of the units are engaged in the manufacturing of 39 items, or 80 per cent of the total reserved production is done in barely 60 items. Even the annual rate of growth in real

terms between 1985-86 and 1987-88 was higher in unreserved items (13.0 per cent per annum) than in the reserved items (10.3 per cent) [Development Commissioner:113].

In the new indirect duty structure say in the Central Budget for 1993-94, particularly in excise duties, the differential levies favouring the SSI units has been considerably narrowed. A review of the daily reports on the apathy of the small-scale sector confronts us with the following general refrain: "Of the many protective and promotional measures initiated by the government in the past, fiscal incentives like excise duty concessions and exemptions have provided the greatest benefits to the SSIs, even more than the reservation of certain items. But these benefits have now been virtually negated with the drastic reduction in excise duties. Further, a large number of products which were essentially produced in the smallscale sector have been brought under the excise net. And some of them now attract ad valorem duties, resulting in higher incidence of excise on them. To add to their woes, bank credit to SSIs has been increasing at a slow pace, much slower than that to medium- and large-scale industries" (The Observer of Business and Politics, July 14, 1994). For instance, any number of examples can be cited from the Central Budget of 1993-94 in this respect. Apart from the drastic reduction in import duties which would have placed some of the small-scale products in a vulnerable situation, it is the rapid reduction in excise duties that would have hurt the relative competitive strength of the informal sector. When excise duties are reduced from

high levels to a range of 5 to 10 per cent on soaps, electric fans and air coolers, radio sets, and on medical equipment, there is no special bargaining strength left with the small-scale units producing these items. So is the case with the complete exemption of excise duty on specified aluminium circles and pipes, or the reduction of excise duty on specified capital goods to 10 per cent or even 5 per cent, or sizeable reduction in duties on paints and varnishes, mechanised matches or small-sized air-conditioners. We have already referred to the CII's pre-budget survey which revealed the sufferance of SSIs in the capital goods sector.

Secondly, a motivating force for the proliferation of SSI units was partly the desire to evade the burden of corporate taxation, which in recent years has lost its rationale. As we brought out in our original paper [EPRF 1995: Table 4 and 1023-1025], corporate tax provision as percentage of profits before tax in respect of the public limited companies in the private sector, which was about 40 per cent in the mid-1980s, came down to less than 20 per cent by 1993-94; the decline had been rather rapid during 1992-93 and 1993-94.

A third major drawback of the reservation policy for SSIs, which has been almost universally recognised, is that the medium and large-scale industries are known to be violating government policy prescriptions because of the absence of appropriate official monitoring, apart from blatant connivance.\* Reportedly, substantial additional capacity has been built up by the organised sector industries in such reserved products as icecream, laundry soap, biscuits, bread, leather shoes, leather sandals, chappals, leather suitcases and travel goods, bright bars, diesel engines (less than 15 HP), PVC pipes including conduits, electric motors (1 HP to 10 HP), different types of paints, various chemical items, paracetamol, tooth paste, and many engineering items. An analysis undertaken by the National Informatics Centre (NIC) of the data thrown by the second census (1987-88) survey shows that of the 21 products chosen for study, the relative share of output of large-scale units was 66 per cent; it was found that in the case of ice-cream, there were 1,188 units in the small-scale sector but only one unit in the large-scale sector produced 94 per cent of the total (The Financial Express, October 31, 1994). Subsequently, by March 1995, it was found that the government of India was contemplating legal proceedings against five large-scale ice-cream manufacturers for violating the SSI reservation norms (The Observer of Business and Politics, May 26, 1995). This has apparently been particularly so after the reform measures have provided the organised private corporate sector with a freer environment from industrial controls and regulations. Apart from offering severe competition to the small-scale industries, this absence of monitoring on the part of the supervisory agencies also has a statistical implication in that it could be the source of under-reporting of output figures by the organised sector itself.

Lastly, the benefits of ancillarisation, both for ancillaries themselves and the SSI units deriving the benefits of subcontracting, would have suffered a setback during the past few years when the governmental and non-governmental undertakings faced severe production cuts. On the question of the PSUs supporting the SSI units in the form of 15 per cent price preferences and 30 per cent purchase preferences as prescribed by the government regulations, it is again widely known that these, particularly purchase preferences, are observed more in the breach because of the absence of monitoring arrangement by the supervisory agencies.

#### INFORMAL SECTORS AND INSTITUTIONAL FINANCE

Overall, the ground reality regarding the regulatory and policy environment for investment and production activities during the post-reform period has been such that the pace of unrecorded growth in the small industry sector would have been considerably hindered. On the contrary, there appears to be fairly conclusive evidence to the effect that the organised private corporate sector has enjoyed better clout and far freer environment for investment and production activities vis-a-vis the informal sectors during this period; the incentives for the organised sector to split and palm off activities into

the SSI sector have also been diluted. Therefore, if the CSO data present a picture of contradictory trends in investment as between the private corporate sector and the informal sectors during the post-reform period, it seems to reflect the ground reality. In this regard, and particularly in regard to the process of facing adjustment pains by different sectors, a factor that would have played a decisive role is the relative quantum of investible resources commanded by the respective sectors — an important aspect of the post-reform macro-economic scene which we wish to spell out in some detail.

To sum up the results at the outset, a detailed analysis of the distribution of institutional finance provides us with a telling story that in the post-reform period it is the organised private corporate sector that has been able to exercise command over relatively significantly larger amounts of investible resources from all sources commercial banks and financial institutions. internal and external sources, domestic and foreign. We already brought out in our earlier paper (EPWRF 1995) how the profitability of the corporate sector had improved due to treasury operations and other incomes, combined with perceptible reductions in the incidence of corporate tax burden as well as interest burden, which have been truly unparalleled in the history of corporate sector performance in India and the benefits of which could not have been derived by the informal sectors to any tangible extent.

To begin with, it is the distinctly higher level of capital market resources and loanable funds from institutional sources

<sup>..</sup> denotes not available; \* RBI Annual Report 1995-96 presents only the supply of agricultural credit by commercial banks: Rs 8,255 crore in 1994-95 showing a rise of 52.8 per cent and Rs 10,172 crore, an expansion of 23.2 per cent, in 1995-96.

available for the private corporate sector vis-a-vis the informal sectors, that would have tilted the balance of bargaining strength in favour of the former. As shown in Table 9, (i) galloping of new capital issues by nongovernment public limited companies between 1990-91 to 1993-94, (ii) large increases ranging from 24 to 31 per cent each year in the disbursements of financial assistance by all-India development banks which generally support the large-scale industry (IDBI, ICICI, IFCI, RBI and SCICI, that is, except SIDBI), (iii) corporate sector borrowings through Commercial Papers (CPs), and (iv) sizeable mobilisation of foreign borrowings through global depositary receipts (GDRs) and other means, all go to show the phenomenal amounts of additional investible resources commanded primarily by the private corporate sector and to a small extent by the public sector undertakings. Contrariwise, there is equally strong evidence to the effect that the informal sectors faced a situation of severe resource constraints since 1991. As shown in the the same Table 9, SIDBI and state-level institutions whose resources are generally earmarked for smallscale (and some medium-size) units, recorded considerably slower growth in their disbursements since 1990-91. Overall, when disbursements of all-India development banks rose by 110 per cent between 1990-91 and 1993-94, those of SIDBI and statelevel institutions together rose by 37 per cent (which is barely equivalent to the 34 per cent rise in the CSO's implicit index of investment deflators).

A more telling and direct evidence in this respect is to be seen in the relative growth of bank credit rendered by scheduled commercial banks to different institutional categories based on data produced by the RBI's system of banking statistics called Basic Statistical Returns (BSR). As brought out in Table 10, the decade of the 1980s saw a significant expansion in the relative share of bank credit in favour of the 'household sector', comprising partnership firms, proprietary concerns, joint families, associations, clubs, societies and groups of individuals and individuals under accounts with credit limit of above Rs 25,000 and all accounts with credit limits of Rs 25,000 and less. The share of the 'household sector' in total bank credit steadily rose from 43.3 per cent around March 1980 to 51.9 per cent towards March 1985 and further to 58.3 per cent as at the end of March 1990. Looking at it differently, between March 1980 and March 1985, the increase in bank credit in favour of the 'household sector' was of the order of 175 per cent as against the total credit expansion of 129 per cent. In the next five-year period again (March 1985 - March 1990), the 'household sector' enjoyed a credit expansion of 144 per cent as against the total credit expansion of 117 per cent. These expansions took place under the impulse of the RBI and government directives regarding the provision of 'priority sector' advances which was placed at 40 per cent to be achieved by the end of March 1985 (alongwith sublimits for agriculture at 18 per cent and weaker sections at 10 per cent). The banks did achieve the prescribed ratio by the end of March 1985/March 1986. In fact, under the policy impulses reflecting societal concerns, the average priority sector share for the banking industry as a whole steadily rose to 44 per cent as at the end of March 1988 but by March 1991, it fell to 39.5 per cent largely because of the loan waiver scheme, the implementation of which was generally completed in March 1991 [RBI 1991; see also EPWRF 1996].

Subsequently, the policy package relating to the financial sector reforms under the structural adjustment programmes kept on assuring that the bank credit needs of agriculture, small-scale industries and other small borrowers would be adequately met; towards that end the 40 per cent priority sector target remained unchanged except for some definitional changes. Under this formal policy prescription, we have the RBI governor warning the banks in his October 1993 credit policy statement, after effecting some modifications in the composition of the 'priority sector' advances, thus: "Failure on the part of the banks to achieve the stipulated level of priority sector credit and/ or failure to show a distinct improvement in the priority sector credit could invite bank-specific policy responses which could include raising of reserve requirements or withdrawal of refinance facilities" [RBI 1993b]. This was emphasised again in sufficiently strong words in the May 1994 policy statement: "I must reiterate that banks

should adhere to the priority sector targets and sub-targets and effective steps should be taken to correct any shortfalls" [RBI 1994]. But, what has been the ground level reality? The share of priority sector advances in total bank credit has steadily fallen from 43.1 per cent in 1990 to 39.5 per cent in March 1991 (due to loan waiver to an extent) and finally to 36.5 per cent by the end of March 1993; there was some edging up to 38.2 per cent by March 1994 [Gol 1995 and 1996]. The deteriorating performance by some of the bigger banks like State Bank of India and the top five nationalised banks has been much more blatant and unsatisfactory in this respect [EPWRF 1996].

The above is yet another case of guidelines intended to favour informal sectors being openly flouted because of the half-hearted nature of official enforcement of those guidelines. In this regard, the RBI's BSR, referred to above, reveal that between March 1991 and March 1993, while total bank credit has risen by 30.8 per cent and that for public sector by 51.7 per cent and private corporate sector by 40 per cent, bank credit for the 'household sector' rose only by 22 per cent (Table 10). In credit limits sanctioned during this period, the differential has been much more sharply tilted against the 'household sector' vis-a-vis the private corporate sector as well as the public sector. As a result, the share of the 'household sector' in total bank credit dwindled for the first time in the post-bank nationalisation period from 57.4 per cent in March 1991 to 53.5 per cent in March 1993 (BSR data for March 1994 and thereafter are not yet available). This has happened apparently under the impulse of the new economic policy which has, as part of the ground reality, decisively turned the tables against promotional and protective measures favour-

ing the informal sectors by emphasising the importance of satisfying capital adequacy norms and other prudential requirements. Impliedly, to reiterate the reality of the so-called incentive structure, the institutional setting and bargaining dynamics created by the stabilisation and structural adjustment programmes of the post-1991 variety has embodied an intrinsic bias in favour of the private corporate sector and against non-corporate and household segments of the economy.

Before concluding this section, it is worth pointing out the relevance of yet another set of data regarding the flow of institutional credit in favour of agriculture and allied industries (Table 11). As Gadgil (1986) put it, there is no gainsaying that "contribution of investment credit to private capital formation in agriculture has been much higher than that of production credit to costs of cultivation" (p 294), or as Rath (1989a:71) put it aptly: "Loan finance has become progressively important in fixed capital formation in the private sector in agriculture, which in turn has become steadily more important in the total fixed capital formation in agriculture over the years" [see also Rath 1989b]. In this respect, it is found that until 1989-90, the rate of increase in loans issued in the form of direct assistance by commercial banks, RRBs and co-operative banks for medium- and long-term purposes averaged almost 15 per cent per annum but during 1991-92 and 1992-93, there were absolute declines of 2 to 3 per cent each year in such loans even in nominal terms.

#### Upward Bias in Household Financial Savings

While seeking to question our hypothesis that the methodology of estimation probably gave rise to an overestimation of household saving in the form of financial assets, A-S

contend that the behaviour of financial savings in 1993-94 could not be considered as an outlier and that household savings in currency and bank deposits in that year were not abnormal, but this contention tends to obfuscate the issue at hand. In the first place, a 'fairly stable' upward trend in the ratio of gross financial assets is not necessarily inconsistent with equally 'fairly sizeable' year-to-year to fluctuations in it. We ourselves had emphasised the phenomenon of 'a steady uptrend' in household saving in the form of financial assets, but at the same time, as we were also dealing with a short-period analysis, we brought out, in the form of marginal propensities, fluctuations in the ratios of incremental financial saving to personal disposable income (PDY) ranging from 0.6 per cent to 38.5 per cent since the beginning of the 1980s. It was the highest incremental financial saving to PDY ratio, in the past decade and a half, of 38.5 per cent for the year 1993-94 that was perceived by us as an outliner; we perceived as such also because we could pinpoint a specific aspect of the estimation procedure that was sure to produce an overestimation of household saving in the form of currency, bank deposits and company shares and debentures for that year.

Without directly confronting the issues raised on the estimation procedure, A-S seek to depend on surrogates, but in the process, stumble into a grave conceptual and methodological error. They argue that the application of historical ratios of sectoral holdings of currency and bank deposits can lead to an overestimation of household financial savings only, not of total domestic savings. According to them, an overestimation of household holdings of currency and bank deposits will lead to an under estimation of the financial savings of some other sector and thus it will only affect the composition of savings, and not the total. This surely shows an incorrect understanding of the relevant concepts and estimation procedure involved.

There are two statements in the A-S paper which are responsible for the apprehensions regarding the improper interpretation of the CSO procedure. Explaining the method of estimation, they state that "...household savings in CSO data (which account for 60 to 80 per cent of total domestic saving) is a residual derived by deducting public and corporate savings (directly estimated from public and corporate accounts) from total saving" (p 2185). Following this statement, they do explain accurately that the household sector's financial saving is arrived at by deducting the government (i e, public) and corporate sectors' holdings of financial assets from the total of such assets in the economy. The sum total of the instrument-wise annual increase in financial assets net of the increase in financial liabilities constitutes household saving in financial assets. However, in the universally-accepted kind of a procedure wherein the stocks of currency and bank deposits are apportioned between nonhouseholds and households on the basis of historical ratios, while the household holdings so arrived at (net variations therein, to be specific) constitute a necessary input for estimating household saving in financial assets and form a constituent part thereof, the balance of currency and bank deposits assigned to non-households are not a constituent part of the estimated saving of the private corborate and public sectors. Their savings cannot be ordinarily apportioned between saving in the form of financial assets and that in physical assets. The savings of public and private corporate sectors are directly estimated briefly as, (i) excess of current receipts over current expenditure for government administration and departmental enterprises, and (ii) retained earnings and transfers to reserves in the case of the non-departmental enterprises in the public sector and all private corporate sector

enterprises and co-operative institutions.<sup>10</sup> Any reference to the portfo!io choices of non-household sectors having a bearing on their savings is not relevant to the issue at hand. Nor is the discussion on year-end bunching of the expansion in currency and bank deposits germane to the estimational issue discussed by us.

Ordinarily, the above clarification would not have been necessary as it is a widely known feature of the saving estimation procedure but another categoric statement made by A-S in their paper, read in conjunction with the statement cited in the previous paragraph, has created a definite misgiving replete with implications for the subsequent interpretation of household saving in financial assets. Arguing that any upward bias in the estimation of household saving in currency and bank deposits can only lead to an over-estimation of household financial savings, not of total domestic savings, they emphasise that "an overestimation of household holdings of currency and bank deposits will lead to an underestimation of the financial savings of some other sector and will only affect the composition of savings" (p 2189). This has no factual basis in the CSO's estimation procedure. What is more, it has no factual basis in any macro-economic analysis where it is generally found that flow-of-funds accounts present public and private corporate sectors as net borrowers while the household sector is the net lender. In a flow-of-funds accounting framework, "households are the only net-saving domestic sector in a modern economy" [Reynolds and Camard 1989]. Surplus financial savings of the household sector go to finance the deficits of the public and private corporate sectors. This is not to deny that private corporate businesses and public corporations as much as households are apt to make definitive portfolio choices in regard to holdings of their financial assets but, first, the private corporates and public corporations as broad institutional categories face excess of financial liabilities over financial assets, and second, a rise in their holdings of currency or bank deposits in any year does not necessarily mean that their savings have gone up; the holdings of such financial assets may go up and yet their retained earnings (i e, savings) may fall drastically or may be nil or negative. Contrariwise, in the case of the household sector, any arbitrary and incorrect apportionment of the increase in currency and bank deposits in favour of that sector will lead to an overestimation of household financial savings and also of total domestic savings; there is nothing in the estimation procedure to counterbalance such inappropriate apportionment. The only counterbalancing factor is the addition to financial liabilities, the estimates of which are generally

independent of the estimation of household financial asset holdings.

Again, on the question of the possible impact of sizeable foreign inward remittances by Indian expatriates on the growth of household saving in the form of money balances, A-S have made no attempt to appreciate the basic distinction we have sought to make between the expansions in money balances attributable to unilateral inward remittances from external sources and those originating in endogenously generated household incomes. In this respect, the bracketing of foreign inward remittances with money wages paid to households is conceptually and operationally inappropriate. Foreign inward remittances inject fresh money balances exogenously into the economic system, whereas payments of money wages by themselves need not do so. An autonomous injection of Rs 100 crore into the economic system through unrequited transfers from abroad, other things being equal, translates into an automatic addition to household saving in the form of financial assets to the extent of say, Rs 70 crore (assuming 70 per cent is the household share based on historical ratios employed for estimation),11 whereas the disbursements of wages to workers do not necessarily add to the stock of aggregate financial assets in the country. Even if the propensity to consume out of inward remittances is high, or alternatively, even if the resulting financial assets are converted into physical assets by the recipient households without much lag, the additional financial assets initially injected into the system autonomously, still circulate unless the monetary policy has made a conscious attempt to contract the circulation of monetary assets. And in the scheme of estimation, so long as short-term monetary assets like currency and bank deposits remain outside the monetary system as constituents of the community's financial asset holdings, or even if they interchange as between different financial assets, a proportion of such assets is accounted for in the estimation procedure as being held by the household sector. In discussions of yearto-year humps of financial assets, the requirement to focus on issues concerning money multiplier and the secondary expansion in monetary assets, their impact on prices and nominal incomes, or the longer term issues concerning the portfolio choices of households, the inflationary and other forces giving rise to larger holdings of monetary assets, the relative yields on alternative assets, or the various theoretical hypotheses like life-cycle, permanent income and their derivatives - explaining household motivations to choose their levels of consumption and saving - all these should not clutter the basic fact that in the current methodology of estimation, autonomous injection of financial assets in reality generally has a distinctly expansionary impact on household financial savings12 unlike in the case of the disbursement of money wages. If, in a year of estimation, certain humps of individual asset accruals externally injected play a distinct role in net changes in total financial assets of the community, they get captured in the estimation of household financial savings for that year, and that too, based on historical ratios of sectoral ownership. While, theoretically, the constant ebb and flow of financial assets of households are influenced by various explanatory factors mentioned above in different degrees and with varied lags, the bloating of household saving in the form of short-term monetary assets should hold good in reality for short period of a year, irrespective of whether the household choices are as between saving and consumption, or as between financial and physical assets.

## IV Postscript and Perspective

As indicated at the outset, we now have the CSO's estimates of domestic saving and investment rates for one more year 1994-95 and the RBI's estimates of household financial savings even up to 1995-96. How do they fare in relation to the earlier scenario of a persistent fall in these ratios and in relation to the broad perspective we sought to provide in our earlier paper based on that scenario? To recall briefly, we had argued that an outstanding and proven aspect of the success stories of the east and southeast Asian economies had been the role of their high levels of initial, and also progressively rising, rates of saving and investment as a contributory factor for their rapid growth during the 1970s and 1980s. But in the Indian case there did not appear to be any sign of improvement in the domestic saving and investment ratios; in fact after three years of reforms the levels of domestic saving and investment remained below what they were prior to the reform process began. More significantly, we went a step further and contended that considering the evolving economic structure and societal propensity as also the public policy framework promoting them, which has served as a constraint on exploiting the saving potential of the community, it is unlikely that the Indian economy would achieve rapid increases in domestic savings in a manner that the successful east and south-east Asian economies achieved as a precondition for rapid economic growth.

In this respect, the broad picture that emerges from the recent trends is that neither the domestic saving rate nor the gross capital formation during the past three-year period

1993-94 to 1995-96 would be higher than that attained during the three-year pre-reform period ending 1990-91 (see Tables 2 and 12). The CSO's official estimates up to 1994-95 suggest an improvement in the gross domestic rate to 24.4 per cent after it fell persistently from the peak reached in 1990-91 at 23.6 per cent to 21.4 per cent in 1993-94. Likewise, the investment rate jumped to 25.2 per cent after it fell from the peak of 27 per cent reached in 1990-91 to 21.6 per cent in 1993-94. However, as has been commented upon earlier ('Overestimating Saving', EPW, June 15, 1996:1424-25), the estimates of saving for 1994-95 are suspect due to a flaw in the estimation procedure. On a detailed study, it is found that the growth in deposits of scheduled commercial banks (SCBs), which constitutes an important component of household saving in financial assets, has been taken for 27 fortnights for the year 1994-95 instead of the usual 26 fort-nights. In addition, the figure for 1994-95 embraced also the year-end closing bulge in bank deposits as the last reporting Friday fell on March 31 in that year. As a result, as depicted in Table 13, the increase in aggregate deposits of SCBs, which went into the saving estimation, galloped from Rs 46,560 crore in 1993-94 to Rs 71,727 crore in 1994-95. On the other hand, the growth of bank deposits for the comparable 26 fortnights would suggest that the absolute expansions were of similar magnitudes during these two years.

Employing the non-comparable set of data as indicated above, the RBI has estimated household saving in the form of bank deposits at Rs 57,426 erore (or 6.1 per cent of GDP) for 1994-95, which was a quantum jump from Rs 29,220 erore (3.6 per cent of GDP). This is truly untenable. It is this flaw in the estimation procedure that contributed to the sizeable increase in household saving in the form of financial assets during 1994-95. It is because of this inflated figure for 1994-95 that there appears a steep fall (from 11.3 per cent to 9.1 per cent) in the household financial savings (net) during 1995-96 – far steeper than what it should be in reality.

In the absence of worksheet inputs into the saving estimation, it is not possible to arrive at an accurate picture of the saving trends, particularly during 1994-95, after smoothing them for the coverage of noncomparable periods.14 However, a rough and ready attempt suggests that the household saving in the form of financial assets appears to have been overestimated probably to the extent of one full percentage point for 1994-95 and by the same token, there may have been some corresponding underestimation for 1993-94.15 Thus, the overall doméstic saving rate may have been stagnant at around 23 per cent during these two years. No doubt, even this level of saving meant a recovery from the depressed level of 21 per cent reached in the first two years of reform 1991-92 and 1992-93, but this recovery has had much to do, as explained in our original paper [EPWRF 1995], with the bloating of short-term liquidity in the system arising from the unprecedented capital inflows, particularly portfolio capital. This is also corroborated now by the RBI's latest estimates of a drastic fall in household saving in financial assets, and possibly in aggregate domestic saving, during 1995-96.

More recent trends in saving and investment referred to above and the nature of public policies pursued thus do not inspire confidence that any significant turning point may be seen in the medium-term in the otherwise sluggish saving scenario. More rapid deterioration than ever before in inequalities in the distributions of incomes and assets, massive growth of rentier and non-functional incomes (as distinguished from wages, genuine entrepreneurial profits and other risk-based earnings), policyinduced impetus to conspicuous consumption amongst the middle- and high-income classes including that through drastic reductions in excise and custom duties on upper-class consumption goods and grant of consumer credit by banks and non-bank financial institutions, and significantly large imports of gold and silver to with the implied leakage in saving, are the important constraints that continue to hold out threat against any rapid improvement in the saving-investment scenario. As has been emphasised by us earlier [EPWRF 1995], any drastic attempt to improve public sector saving, desirable as it is, may nevertheless, under the present social milieu, adversely affect household disposable incomes and in turn household saving.

#### Notes

[Extensive help rendered by Bhagyashree Mandke and Paramita Debnath in the preparation of this note is gratefully acknowledged.]

- 1 This is the general view in the context of the developed as well as the developing countries "It is to be expected -. that the flow-of-funds accounts (FFAs) will provide a more comprehensive coverage of household savings than do the national income and product accounts (NIPAs) This is because the accumulation of financial assets and liabilities of households is directly covered by the financial accounts (except for informal transactions, many of which are interhousehold flows that would net out in the accounts anyway) Also, while the informal sector of the real economy may escape reporting in the NIPAs, the financial flows that they permit may well be captured in the FFAs as changes in financial savings of the producing units (which appear as households)" [Reynolds and Camard 1989.166].
- 2 Through a slightly different perspective, the impact of underground activities on saving

- is said to be minimal. See Wilson et al (1989) 140): "Thus, only when NIPA expenditures are estimated on the basis of methods that already implicitly include payments to 'underground' sellers of services - for instance, payments for repair and maintenance of residential houses - would the addition of the 'underground' income of the seller of such services add to saving Otherwise, the omission of underground activities from the statistical sources used in the preparation of the NIPAs likely reduces the estimates for income and expenditures by the same amounts, leaving the estimate for personal saving unchanged From the FFA perspective, there is a similar balancing of sources and uses of funds Consequently, the omission of underground activities in the NIPAs may not affect the difference between saving estimates in these accounts and those in the FFAs"
- 3 The story of what was revealed by the only census of public limited companies that the RBI conducted in the 1970s and the problems associated with the blowing-up factor for the global estimation of private corporate sector saving and capital formation, as also the absence of satisfactory paid-up capital series and poor quality of sample for private limited companies, are all an indication of these misgivings [See RBI 1982, 71-74 and Rama Rao 1990 219-225]
- 4 The Raj Working Group (p 49) quotes a report produced by the USA's National Bureau of Economic Research (NBER) in 1958. Interestingly, the NBER's most recent study continues to air a similar view. See Lipsey and Tice (1989: 9-10) "However, the saving data, particularly the sectoral estimates, remain a weak element in the accounts, . the quality change adjustment issue remains controversial and unsettled, and the discrepancies among saving estimates from different sources remain enormous" The same theme is expressed in Reynolds and Camard (1988 161-162) "Household savings are always among the weakest figures in the NIPAs, even in industrial countries with well-developed statistical agencies, and the discrepancy between NIPA and FFA estimates can be considerable. In Latin America, NIPA household savings have long been thought to be understated . . and are subject to substantial upward correction when matched with the comparable figure from FFAs'
- 5 "Effort has also been made to make use of as much current data as possible in place of utilising the proportion based on old bench mark surveys—specific mention may be made of the follow up of surveys of the Economic Census (EC). The EC and its follow-up surveys have been specifically designed to fill in data gaps pertaining to unorganised segments of the non-agriculture sectors of the economy" [CSO 1988—2-3, see also Gothoskar 1988 2014]
- 6 We do not rule out the possibilities of estimational errors in foreign capital inflows, but their size and direction should be of the same genre as the other sources of sources and hence unlikely to alter the trend revealed in the official data
- 7 As per the Annual Survey of Industries (ASI) for 1992-93, 66 per cent of the number of factories, 13 98 per cent of the gross factory output and 2 69 per cent of the total fixed

- capital belonged to the institutional categories constituting the 'household' sector.
- 8 "That apart, the bigger enterprises have got into the product lines reserved for SSIs using the lacunae in the 1970 administrative order that put a number of products on the reserved list. The Union Industry Ministry's order lacked the weight of law though it was only a decade and more later that the Bornbay High Court struck down the reservation policy as null and void. Thus, for a long period those units which should not have been around were producing the reserved goods openly on the strength of carry-on-business licences and covertly through their small-scale subsidiaries. A study in 1984 by the corporate policy group of the Indian Institute of Public Administration had listed several such instances to make a case for tighter monitoring of the reservation policy. It was only after the high court's ruling that the central government acted to get an ordinance issued. But a long period of wilful neglect of glaring loopholes in the reservation policy made a mockery of the very idea of giving small and tiny sectors a fighting chance" ('Small Must Be Beautiful'. Financial Express, October 24, 1994).
- 9 This is not contradicted by the upward revision for 1993-94 in the household physical assets formation from 5.6 per cent of GDP in the 1995 NAS to 6.6 per cent in the 1996 NAS (Table 3). This revision coincides with a corresponding downward revision in the GCF estimation for private corporate and public sectors together, thus, possibly proving that the household sector is the 'dumping ground' for estimational errors in the aggregate GCF as well as those in the estimates for the organised sectors. This expression is found in Holloway (1989, 146) Such year-to-year revisions are also a common feature in the estimates for the US. See Wilson et al 1989. To an extent, this may explain the 'stylised fact' of the sectoral behaviour of capital formation in India, as pointed out by Joshi and Little (1994, 315) and A-S (1995, 2185-2186)
- 10 This problem is confronted by all countries which combine data generated from flow-oftunds accounts (FFAs) with those generated from national income and product accounts (NIPAs) See Lipsey and Tice (1989: 11-12). "In other words, financial saving is the net acquisition of assets less the incurrence of habilities; measured saving thus includes measurement errors in both acquisition and disposition of assets and issuance and retirement of liabilities. Here, too, the household sector is mostly derived as a residual, by subtracting known holdings by businesses and governments from known totals outstanding for most assets" See also Holloway (1989) on the government surplus or deficit of government saving and undistributed corporate profits as saving of the corporate sector in the NIPA For a comparison of the personal saving estimates under NIPAs and FFAs framework, see Wilson
- 11 An example somewhat close to this phenomenon is found in the case cited of the influence of inward and outward capital flight between Latin American countries and the US residents in the following statements of George M von Furstenberg (1989: 150): "Funds that originally had arrived through

- capital flight may not have been identified as claims against the US, being credited instead to US residents - perhaps friends, relatives, or their proprietorships... Assuming the foreign private capital arriving in the US would, in good part, be (mis) represented as being owned by US residents once again, there would be an overstatement of household uses of funds in the US that is coupled with an understatement of capital imports". A similar example given by him relates to the ebb and flow of dollars through the drug market (p 151): "In reality, however, the undetected leeching of currency from the US into foreign hands leads to an overstatement of monetary assets owned by US households. Financial uses are then overstated also because they are determined by differencing estimates of stocks at different points in time".
- 12 In such a discussion, the consequences of increased monetary assets on nominal GDP and hence on the ratios of saving and investment to GDP are not of direct relevance.
- 13 There may have been a slight revision in the bank deposit data and hence the household component in it, but the details are not available.
- 14 There could be various methods of smoothening such irregular series such as the use of annual averages, averages of a few year-end fortnights or March 31 data. The change would, of course, have to be considered carefully and the time-series recast accordingly on a consistent basis. Mihir Rakshit (1982 and 1983) had raised the issues associated with the bunching of large-scale payments towards the end of the financial year "which will lead to an overestimation of saving of the unorganised sector". We are not seeking to address the fundamental questions of the appropriateness of the existing methodology of estimation in this regard in the present paper
- 15 This is on the assumption that the estimation should be based on March 31 figures of bank deposits as indicated in CSO 1989
- 16 Imports of gold, which ranged from 150 to 170 tonnes during the three-year period 1989-1991 (clandestine), galloped to a range of 304 to 384 tonnes during the past four years 1992-1995 (both official and clandestine). At 384 tonnes, the import value works out to approximately Rs 18,000 crore at domestic prices.

## **Savings Rate in Indian Economy since 1991**

#### Pulapre Balakrishnan

It has been widely noted that the estimated household saving rate has declined for almost three years running since 1991. This has been interpreted variously. The government of India has rushed to argue that the 'measured' decline might only reflect a methodological practice. On the other hand, critics of the reform process have argued that the decline is not only real but a direct consequence of the strategy adopted which has encouraged increased consumption of durable goods.

Both these arguments are considered here and found wanting. On the other hand, the behaviour of the household savings rate since 1991 is relatively well explained by a persistence of consumption in the presence of an unanticipated shock in income. The decline in income is itself not too difficult to explain. It is often overlooked that since 1991 the economy has seen not only reforms but also a conventional stabilisation programme that initially lowers growth.

"...a man's habitual standard of life usually has the first claim on his income, and he is apt to save the difference which discovers itself between his actual income and the expense of his habitual standard."

- J M Keynes, The General Theory

'HIS study is concerned with the behaviour f the savings rate in the Indian economy 1 recent years. The first point to note when onsidering the behaviour of the savings rate 1 recent years in the Indian economy is that nere is a multiplicity of estimates of savings choose from, Naturally, therefore the uestion of which estimate one uses assumes aramount importance. An approach to hoosing among the sources is provided by ne well known Working Group on saving ppointed by the government of India in the arly 1980s: "The most detailed and omprehensive estimates of saving and apital formation now available, published y the Central Statistical Organisation (CSO), re the outcome of a series of attempts from ne latter half of the 1950s to generate and mprove the estimates of various components if national income; they are also the most videly accepted official series, though the 'lanning Commission and the Reserve Bank of India have continued to publish estimates ften slightly at variance with them" [RBI 982:1]. This view, though dating to 1982, vould find wide acceptance in India even oday. The savings estimates used in this tudy are therefore those put forth by the CSO.

#### I Savings Rate since 1990

In Table 1 are provided the data on the iggregate savings rate in the Indian economy and its decomposition by 'institution'. Some of the features may be noted. First, ignoring the reluctant increase in 1993-94, the gross domestic savings rate in the Indian economy has declined steadily since 1990-91. This is mirrored by the decline in the household savings rate. The savings rate of the public sector, which comprises the government administration and the public sector undertakings, has behaved more erratically,

but declines steadily after 1991-92. To digress briefly, with hindsight it can now be said that the dramatic improvement in 1991-92 of the public savings rate reflects the reiningin of the budget deficit in that year as part of the imperatives of macro-economic stabilisation. Finally, in contrast to the behaviour of all the other savings rates, the rate of savings in the private corporate sector shows a more or less continuous increase since 1990-91.

#### SAVINGS OF HOUSEHOLD SECTOR

In Table 2 is presented evidence on the composition of household savings. The classification is, of course, that provided by the CSO, and the only one available. It decomposes aggregate savings by households into savings in the form of financial assets and savings in physical assets.

## II Estimation of Saving and Investment in Indian Economy

Investment: For the estimation of capital formation (and consumption) in the Indian economy the CSO employs the commodity flow method. Estimates of the value of construction, machinery and equipment and of changes in stocks for each of these two activities are made separately. Thus, capital formation is measured from data relating to production, export and import of items going into this category of investment and from estimates of the changes in stocks of these goods. In the case of 'construction' a base measure of the total value is obtained by inflating the estimated value of materials used and adding to this factor incomes.

Savings: When it comes to the estimation of savings, the economy is divided into three sectors and the savings of each estimated separately, and not always by the same method.

The reconciliation: Where a discrepancy arises between the estimates of aggregate domestic savings plus net capital inflow from abroad and that of domestic capital formation the former is taken as the

controlling total and the discrepancy is treated as 'errors and omissions'

A more elaborate exposition of the method of estimation is required and is best provided in the Report of the Working Group on Savings:

To begin with the economy is divided into three broad sectors: the public sector, the private corporate sector, and the household sector. Since the first two belong to the 'organised' segment of the economy, estimates of both saving and capital formation at current prices can be made for these sectors from the published government and company accounts; and, if all the relevant documents are available for this purpose, it should be possible in principle to avoid any significant errors in estimation. The problem arises primarily in regard to the 'unorganised' household sector, for which such information is not easily available; it needs to be noted this is of relevance when assessing the evidence] that this sector includes conceptually not only farm households engaged in agricultural production but all unincorporated enterprises engaged in industry, trade, transport and finance, private 'charitable' trusts, as also households that are not directly involved at all in production of any kind (except very marginally perhaps through ownership of residential houses). The estimates for this large, heterogeneous, and unorganised segment of the economy covered by the household sector are essentially in the nature of residuals derived by deducting the saving and investment estimates for the public sector and private corporate sector from estimates of aggregate saving and aggregate investment independently arrived at for the economy as a whole. This makes it a matter of crucial importance how these aggregates are estimated

The first step here is to estimate aggregate domestic investment in the economy each year. This is done by identifying three important forms in which physical assets can be accumulated (such as steel, cement, machinery and equipment) and/or the expenditures associated with such accumulation. What needs to be noted here is that, while it is relatively simple to compute the available quantities each year of the main commodities that go into fixed capital

formation, there can be large margins of error in estimating the total capital outlay with which they are associated since they would depend on the correctness of a variety of norms used for this purpose. In the case of inventories also, while estimates of investment in the public sector and in some of the major industries in the private sector can be made without much difficulty, estimates of inventory accumulation in the rest of the economy are much more problematic. Consequently, the possible errors in estimation of aggregate investment in the economy are not only sizeable but, in the present state of our statistical data base, quite indeterminate. The gross investment in the public sector and in the private corporate sector can be independently estimated from published accounts (as indicated earlier), and this is precisely what is done at the second stage. But when gross investment in the household sector is derived at this stage as a residual, all the errors in estimation of aggregate investment in the economy (done in the first step) and such errors as might enter into the estimates for the 'organised' segment are necessarily carried over to the estimates for this sector. Consequently these estimates of investment in physical assets within the household sector are subject to a possibly significant and necessarily indeterminate degree of error [RBI 1982:3-4]

An accessible diagrammatic representation of the estimation method described above appears in the Report of the Working Group and is recommended viewing for its conciseness. What has been provided here leaves out much of the detail. The ultimate source, of course, remains National Accounts Statistics – Sources and Methods produced by the CSO 1989.

One point that may be seen to emerge from the discussion so far is that the methodology of estimation ensures that the savings of the household sector in terms of physical assets is identically equal to the (unadjusted) estimate of gross capital formation in the household sector. This may have implications for the question that we are seeking to study - the plausibility of the decline in the household (physical) savings rate.

#### III Sources of Bias in CSO's Estimate

Investment in 'Construction' and 'Machinery and Equipment'

The method of estimation of the gross capital formation in the Indian economy is the 'commodity-flow' method. The competing methodology, of course, is the 'expenditure' method of national income accounting. Clearly, it is because of the infeasibility of adopting the expenditure method that the CSO uses the commodity-flow method. Even at the outset we can see the limitations of using the same method for

estimating the value of heterogeneous types of 'construction' and the use of arbitrary ratios of the output of 'partly capital goods' such as furniture and fixtures, locks, cameras, etc, as investment.

Now let us take a slightly more detailed look at the method of estimating the value of construction. For this, the CSO considers two types of construction: 'pucca' and 'kutcha'. The value of 'pucca' construction in any one year is arrived at as follows: (1) Estimate the production of the five basic materials used in construction activity: cement, iron and steel, timber and roundwood, bricks and tiles and permanent fixtures and fittings. (2) Estimate the total material cost of construction by the use of a given ratio of the five basic materials mentioned above to total materials cost. The ratio is taken to be 65.9 for 1970-71. (3) Now work out the total outlay on construction by assuming a certain ratio of factor incomes to the cost of material inputs. The ratio is taken to be 60 per cent for 1970-71.

The ratios mentioned are adjusted from year to year to take into account changes in the relative price of the five basic materials mentioned above and the rest and the relative variation in wage rates and the prices of materials used in construction.

Kutcha construction is estimated by assuming that its value stands in a certain fixed relation to that of the corresponding pucca construction.

Rakshit (1982, 1983) has pointed to three possible sources of bias in the estimation of gross capital formation in construction by the commodity-flow method of the CSO:

- (a) Labour-augmenting technical progress and the greater use of the five basic materials due to the shift to high-rise construction is likely to have altered the ratio of basic materials to both the total and wages. With the ratios remaining constant, these changes lead to an overestimation of factor incomes and the cost of materials other than the five basic ones used in construction.
- (b) The fixed proportions used in deriving the value of kutcha construction are mostly ratios based on sample studies conducted in the late 1950s and the early 1960s. Since the ratio of kutcha to pucca housing may be considered to have declined over the three decades, a systematic overestimation of the value of the former may be expected.
- (c) The commodity-flow method can overstate the use of the five basic materials used in construction and thus lead to an overestimate because it does not correct for change in stocks, and 'the change in stocks' is already counted as capital formation. Though this occurs when the commodity-flow method is used in the estimation of investment in machinery and equipment also, unlike in the case of 'partly capital goods' that constitute investment, an overestimation of the five basic building materials has a

multiplier effect for these materials are first evaluated as inputs into pucca construction and then kutcha construction is evaluated as a fixed proportion of this overvalued outlay on the pucca. Rakshit calculates that for one cagegory of construction the multiplier associated with the overvaluation can amount to as much as 3.13.

Valuation of imports and estimation of capital formation

It is widely recognised that controlled trade and exchange rate regimes lead to false reportage of the value of trade, and indeed many foreign exchange transactions. However, it is the overinvoicing of imports done with a view to gain access to scarce or rationed foreign exchange that is relevant to the problem of estimating domestic capital formation. For instance, the underinvoicing of exports does not affect the estimated value of machinery or equipment available for domestic capital formation, nor would the false reporting of the import of goods other than capital goods. But false reporting of capital goods imports can affect the measure sought. Nevertheless, and this is directly relevant to the issue that we are concerned with ultimately in this study, it has no effect on household saving. An appreciation of this is necessary when confronted with the plausibility that the incentive to overinvoice may have decreased after the progressive freeing of the rupee

Table 1 Composition of Aggregate Savings

| Year    | Aggre-<br>gate | Public | Private<br>Corporate | House<br>hold |
|---------|----------------|--------|----------------------|---------------|
| 1990-91 | 23 7           | 1.0    | 2 7                  | 20.0          |
| 1991-92 | 23 0           | 2.1    | 3 2                  | 17.8          |
| 1992-93 | 20.0           | 1.5    | 3.0                  | 15.5          |
| 1993-94 | 20.2           | 0 2    | 4 0                  | 16.9          |

SINCE LYVI, at least for current account transactions.

A clear statement of the implications for the estimation of capital formation of the incorrect reporting of the value of imports appears in Rakshit: "Overinvoicing in respect of imports of capital goods, on the other hand, directly results in an overestimate of investment under the commodity-flow method. Note, however, that since capital goods are imported almost exclusively by their final users in the private corporate and public sectors, an upward bias will arise in the estimates of either non-household saving or net capital inflow from abroad... It thus appears that inflated accounts of investment costs on the part of producers in the private corporate and public sectors can, after all, produce an overestimate of domestic capital formation even under an otherwise foolproof commodity flow method, if the overstatement of costs relates to the imported component of investment projects" [Rakshit 1982:569, italics added]. This aspect must be borne in mind when evaluating the possible implications for the estimate of capital formation of the removal of the incentive to overinvoice imports after the freeing of the tupee on current account since 1991.

## Two Views on Recent Behaviour of Savings Rate

The first point to take note of when considering the measured decline in the savings rate since 1991 is that the behaviour of the savings rate in India has posed a problem to economists even in the past. For instance, the very considerable rise in the savings rate alongside stagnant growth during the 1970s had generated much attention a little over a decade ago [Rakshit 1982]. So it is not as if the most recent period is egregious by virtue of the non-constancy of the savings rate that has been observed. In fact, as I shall argue, it is relatively easy to provide an economic explanation of the behaviour of the savings rate in recent years. This is done by means of a simple econometric model. But prior to that I consider two arguments that have been made regarding the behaviour of the household savings rate in the Indian economy since 1991.

### (a) The household saving in physical assets is underestimated.

Athukorala and Sen (1995) argue that the measured household physical savings rate is very likely an underestimate, and that the decline in the savings rate is an artefact. Given the definitional equality between household capital formation and household saving in physical assets, i e, they are the same thing, Athukorala and Sen conduct their entire argument in terms of 'household

capital formation'. They start by referring to a divergent pattern in the behaviour of household and private corporate capital formation and argue that this is untenable. They then state that this divergent behaviour is a sort of 'stylised fact' for the Indian economy and that ergo it points to an estimation bias in the CSO methodology: "The negative relationship between the two investment rates is, therefore, difficult to explain in terms of economic behaviour. Since the estimates for private corporate investment can be considered to be more reliable (obtained as they are from the RBI's sample of firms), one can expect that in a context where corporate investment exhibits an increase (decrease) any underestimation of gross domestic capital formation by the commodity flow method in a given year would result in a spurious downward (upward) movement of household capital formation (and therefore household saving in physical assets) in that year" [Athukorala and Sen 1985:2186].

The first problem with this argument is that it is ad hoc. Naturally, if the CSO measure of gross capital formation is an underestimate 'in a given year', then the rest of the argument follows. But the point is to suggest why the CSO methodology is prone to underestimate gross capital formation for the period since 1991 A second thrust that the Athukorala-Sen position must deal with is an empirical one. This is that in at least one of the years in the sample, the divergent movement in private corporate and household capital formation holds but barely. In 1993-94 the value of household saving in physical assets takes a large fall at a time when corporate saving is more or less steady. Since the 'underestimation' argument is based on an accounting relation it must hold without lags, and it would be hard put to explain this contemporaneous behaviour that I have referred to. But the more difficult point to accept is the Athukorala-Sen suggestion that from the 1990s on the CSO methodology begins to underestimate capital formation, or if an underestimation already existed its extent actually increases from 1991. It is in sharp contrast to the Rakshit view that the commodity-flow method of estimating capital formation is very likely an overestimate. Rakshit has provided reasons for his conjecture [Rakshit 1982].

Athukorala and Sen (1995) provide two explanations of why "... recent developments in the Indian economy since 1991...render the old methodology of measuring capital formation vulnerable to measurement errors..." [Athukorala and Sen 1995:2188] I shall evaluate them even as I state them. First, they refer to the "ongoing process of 'informalisation'" of Indian industry since the early 1980s and quote Ahluwalia to suggest that "...small industry is the home of unrecorded growth..." [Athukorala and Sen 1995;2188]. Then they argue "In a context where the relative contribution of informal sector production units continue to grow at a rapid rate, estimates based on the commodity-flow method are likely to understate domestic capital formation, unless the estimation procedures are revised on a continual basis to capture construction material, machinery and other investment goods produced in the unorganised sector" [Athukorala and Sen 1995:2188] This line of reasoning is unhelpful for three reasons First, it is difficult to imagine cement and iron and steel, the principal building materials in the CSO's schema, not to mention any significant range of investment goods, being produced in the unorganised sector. Secondly, even if the CSO is missing out on the commodity flows originating from the unorganised sector so it must miss out on income generation - this being, ostensibly, the home of unrecorded growth - and since we are concerned with the rate of capital formation we would have to make strong assumptions regarding relative rates of growth of capital formation and income, respectively, to generate a declining rate of capital formation. But more damaging for

- Reserves jump from 75% of haid-up capital to 266% (including revaluation reserves of Rs 580 crores).
- Capital adequacy 9 5%
   Non Performing Assets below 6% of total advances (net of provision)
- Branch network 2004, up by 95 branches
   Loss making branches -only 3 out of 2004 as against 16 last year

The Bank more or less doubled its size in business mix between March'93 and March'96, from Rs.13,000 + crores to Rs.27,000 + crores Solid with Ilquidity of Rs.300 - 500 crores at any given point of time throughout 1995-96 - the year of the crunch

## UNION BANK OF INDIA

Good people to bank with

this process of informalisation was believed to have gathered pace were a period of sustained growth of the rate of saving in physical assets in the household sector [RBI 1982]. The second explanation provided by Athukorala and Sen (1995) is that there has been a rapid growth of capital (and intermediate) goods imports as a result of import liberalisation since 1991. "This rapid growth in the post-reform period implies a continuous increase in the share of imported capital goods in total domestic availability of capital goods. Given the time lag involved in the compilation of trade data, it is likely that the estimates of total fixed capital formation obtained by using a historical ratio of imported to total available capital goods understate increases in capital formation based on imported capital goods in the post-reform economy, at least in the most recent year for which data is reported" [Athukorala and Sen 1995:2189]. Athukorala and Sen do provide some evidence of the rate of growth of capital goods imports but none to establish that the ratio of imported to domestically produced capital goods that enter fixed investment has increased.

In Table 3 are provided data on the rate of growth of the import of machinery. Since the original data are in values we cannot, of course, be certain that the rates of growth necessarily translate into higher numbers of goods, but let us assume for a moment that this is the case. Let us further assume that the CSO always works with historical ratios of imported to domestically produced capital goods, and that this is always a couple of years outdated as Athukorala and Sen suggest. Then, comparing these figures with those for the growth of these segments of Indian industry [Economic Survey 1994-95] it appears that, over the sample period, there would be both an overestimation and an underestimation, respectively, depending upon the year chosen. This is a rough and ready exercise, especially since, as I have already mentioned, the data is for values while any argument pertaining to the commodity flow method must refer to quantities. But nevertheless, we can say with some confidence that the argument that the CSO methodology, based as it is on historical ratios of imported to domestic machinery, would have underestimated capital formation in the years since 1991 is very definitely false at least for the year 1991-92, the year in which household saving in physical assets shows its largest decline. In that year the behaviour of imports and aggregate capital formation in the economy move in the same direction.

But let us assume, for the sake of argument, that there is divergence in the rates of growth of imports of capital goods and of the production of their domestic counterparts. Now even if this were the case, there is little

Dasis for the Annakorala-Deli argunichi that this would underestimate aggregate capital formation. Only because the CSO's stated methodology makes no reference to historical ratios of imported to domestically produced capital goods in capital formation. I cite from the CSO's statement of the methodology: "To the ex-factory value of capital goods produced domestically, the amount of excise duties, imports and import duties are added. From the total thus obtained, the value of re-exports is deducted to obtain the availability of capital goods. The value of capital goods so obtained is then marked up for trade, transport and other charges to obtain the value at purchasers' prices. Trade, transport and other installation charges have been estimated for 1980-81 on the basis of data collected from leading manufacturing firms in the country. From the total value at purchasers' prices thus obtained, the value of exports is deducted to obtain the value of capital formation at site" [CSO 1989:234]. It is clear from this statement of the methodology for the treatment of imports in the estimation of capital formation that there is no basis for the argument that it is prone to bias as the ratio of imported to domestically produced capital goods alters. This ratio just does not enter into the picture.

Finally, the Athukorala-Sen argument draws its significance from a claimed inverse relation between measured capital formation in the private corporate and the household sectors of the Indian economy - a "stylised fact" in their view. Now, it is certainly the case that for the three years since 1990-91, household saving in physical assets has declined even as private corporate investment has increased. This, it is suggested, is a sure sign of the bias in the CSO methodology. It is also indeed correct that given the estimate of private corporate investment the appropriate measurement of aggregate capital formation in the economy is of significance to the estimate of household saving in physical assets, the latter estimate being in the nature of a residual. However, a closer look at the relevant figures for gross domestic capital formation as a percentage of GDP at current prices by institution over a longer period reveals that an inverse relation is evident only in the 1960s - during which period the household saving in physical assets increased while private corporate investment decreased - and that this is not so in the 1950s and 1960s [RBI 1982: Table 4.3]

(b) The household saving rate is correctly estimated and it has declined for a plausible reason.

There is the view that the reforms have contributed to the decline in the savings rate by leading to increased consumption expenditure, especially expenditure on consumer durables. This is easily tested, at

icasi ai ilic rudimentary ievei. In 1 abie 4 are provided annual expenditure by broad consumption groups. We find that the annual average rate of growth in the expenditure on consumer durables is perhaps higher during the 1980s than it has been in the period since 1990-91. For more conclusive evidence the figures in Table 4 are converted into percentage shares of aggregate final consumption expenditure and the evidence is presented in Table 5. We now see that while the percentage share of durables is certainly higher than it was in 1980-81 it is substantially lower than it was in 1990-91. There appears to be little evidence that increased expenditure on consumer durables, or even semi-durables for that matter, have led the increase in consumption that implies a reduced rate of saving.

Even though the evidence represented by final expenditure on durables is fairly conclusive, it would be of interest to seek the exact counterpart figures on production. These are presented in Table 6. The evidence is so clear-cut that it is not necessary to discuss it. There is little basis for the view that the proliferation of consumer goods, the increased production of which was unleashed by the liberalisation process, has contributed to the decline in the savings rate. Consumer goods remain on the banned list of imports so the data on production alone is relevant here.

While the evidence does not support the view that the savings rate may have declined

due to the increased expenditure on durables we cannot rule out an increase in expenditure on one important item considered consumption in the Indian system of national income accounting. This is expenditure on gold. Among the macro-economic reforms in the Indian economy since 1991 has been the relaxation of the import of gold. Insufficiently well understood, the policy was geared to prevent unobservable capital flight, referred to as 'hawala', and thus to pave the way for the final floating of the rupee. While accurate estimates of the import of gold into the economy and thus the increased expenditure on the same following upon the relaxation of imports are not available, it is widely believed to have increased. The World Gold Council provides estimates of the consumption of gold by major consumers of the metal. Figures from the Council's Report for 1994 are cited in Vaidyanathan (1996). These suggest that the demand for gold in India is only a little less than the combined demand of China and Japan. Since India produces little of the metal the greater part of gold consumption has to be imported. The World Gold Council's estimates of consumption of gold has been used in the estimate [Sinha 1996] that Rs 20,000 crore worth of gold was imported in the year 1995. The saving of the household sector in the year 1994-95 amounted to Rs 1,78,696 crore ICSO 1986: Statement 6]. Since the figures on gold consumption are imperfect estimates they are to be seen here only as providing perspective. In this light, we can now see that with expenditure on imported gold alone exceeding 10 per cent of household saving substantial shifts in the household expenditure on gold can affect the measured savings rate. This is so because expenditure on gold is treated as consumption under the national income accounting procedure adopted.

However, the important task of providing reasons for an increased propensity to expend on gold remains. Liberalisation of gold imports was announced only in March 1992, in Manmohan Singh's second budget, and was to be applicable from the year 1992-93 on. So it cannot account for the decline in the savings rate starting 1991-92. Finally, the argument that the heightened uncertainty in the economy since 1991 has been reflected in the increased hoarding of gold thus accounting for the decline in the measured savings rate is plausible but difficult to verify.

## V Behaviour of Household Savings since 1991: A Suggested Interpretation

Among the views considered so far in this study are: (1) that the decline in the savings ratio is an 'artefact' the result of faulty estimation and (2) the decline in savings is real indeed and brought about due to

increased consumption expenditure, in particular, expenditure on consumer durables the production of which was impelled by the liberalisation of the Indian economy, Taking up the latter argument first, we find little evidence for it. Quite simply, expenditure on consumer durables has not led aggregate consumption expenditure during this period. I have also considered in some detail the arguments put forward for the view that the CSO methodology per se underestimates capital formation and thus household savings, and concluded that these are not satisfactory as accounts of why the measured rate showed a decline. One source of underestimation can however be thought of and I do so in due course. But first I consider the possibility that, assuming the estimation to have been done right, there may yet be a plausible explanation of the behaviour of savings in the period since 1991.

A clue to the understanding of the behaviour of savings in the Indian economy since 1991 is provided by looking at a slightly longer time series. Two features emerge. First, a decline in the aggregate savings rate accompanied by a decline in the rate of saving in physical assets by the household sector is not a new phenomenon in the Indian economy. It is a feature countenanced also in the second half of the 1950s [RBI 1982: Statistical Annexure 1]. Interestingly, as at present, this coincided with a major policy initiative - the launching of the heavy industrialisation programme associated with the Second Five-Year Plan. So neither quick resort to arguments of faulty estimation nor the argument regarding the easy availability of consumer goods is inevitable, as it were. The second of the two features that I refer to may well contain the clue to the observed decline in the savings ratio. That is, the savings rate appears to be related to the rate of growth of the economy, among other things. This has been remarked upon, in a similar context in the past, by the Working Group on Savings and I quote: "In the period since the middle of the 1970s there have been some other special factors that could explain the quickening of the rate of saving in the household sector. One is simply the higher rate of growth of national income in the four-year period from 1975-76 to 1978-79; during this period the average rate of increase of real income in the economy

was as high as 6.5 per cent per annum" [RBI 1982:47].

Now the decline of the savings rate since 1991 is no longer so difficult to explain. This period has seen a slowing down of the rate of growth of the economy. The rates of growth of GDP and of the manufacturing sector are presented in Table 7.

It has long been recognised that an implication of the life-cycle theory of saving is that the proportion of income saved is a function of the contemporaneous rate of growth [Farrell 1959]. This was first tested by Houthakker (1965). Later Modigliani (1970) exploited this idea to explain intercountry differences in the savings rate. The relationship between savings and growth has been recently re-examined by Carroll and Weil (1993). They write: "...in a comprehensive study of the determinants of saving rates in the OECD countries in the period from the 1960s to the 1980s, Bosworth (1993) found that the growth rate of income was the most important determinant of saving. Looking over longer spans of time, Maddison (1992) also finds a positive relation between saving and growth." Interestingly, as reported by Carroll and Weil, among the economies in the Maddison sample is India over the period 1890-1913. Now it is well known that the correlations that these are based on cannot establish causality. This is an important issue. For instance, in the neoclassical model of growth epitomised by the work of Solow, higher saving will lead to higher growth, thus producing a positive relation. Carroll and Weil try to resolve this by the use of Granger-Causality tests which they report as favouring the view that income growth causes saving. Now, of course, the question of the precise mechanism is to be faced. Obviously the underlying consumption function is the issue. Carroll and Weil point out that a version of Modigliani's Life Cycle Hypothesis with habit formation and uncertainty regarding income can account for the observed behaviour. Essentially, given a previous habit stock, consumption will adjust only sluggishly to changes in income. They do, however, acknowledge that while habit formation could potentially cause a positive relation between short-term growth and saving, for this result to materialise the 'habit stock effect' ought to be large in relation to

TABLE 9: CAPITAL FORMATION BY INSTITUTION

(Current rupees crore)

Note: 'Constn' is Construction and 'Plant' is Machinery and Equipment in CSO parlance. Source: Adapted from 'Statement 19', CSO (1995).

the 'human wealth effect' of growth which tends to increase consumption.

As a test of the hypothesis for India I first estimate the following model for the period 1951 to 1994:

$$S_1 = a_0 + a_1 \Delta y_1 + \varepsilon_1$$

where s is the household savings rate,  $\Delta y$  is the rate of growth of real income, and  $\epsilon$  is the error term.

Subsequently, it is re-estimated for the period up to 1991, used to forecast the savings rate for the three years that follow, and tested for parameter stability. Since the Life Cycle Hypothesis concerns personal savings, as opposed to corporate or government saving. the dependent variable is the savings of the 'household' sector of the Indian economy. Note that while so far in the argument I have used the framework of the CSO and discussed the household savings in physical assets and in financial assets separately, the econometric model is specified with aggregate household saving as the dependent variable. This is done on the understanding that while the separation of aggregate saving of the household sector into saving in financial and physical assets may be a convenient factor in estimation it is not a classification with any economic-theoretic content, for an explanation of how households arrive at their chosen allocation between the two types of assets remains. This point has been correctly stressed by Rakshit (1983) in his review of the report of the Working Group on Savings. The data on savings and on the rate of growth (of GDP at factor cost at 1980-81 prices) is taken from the Economic Survey 1994-95. The ordinary least squares estimates are reported in Table 8.

In the estimate, the coefficient on the growth variable  $\Delta y_i$  is positive suggesting that we are not off the mark in hypothesising that the savings rate is influenced by the contemporaneous rate of growth. Further, when the model is re-estimated for the period 1950-51 to 1990-91 and used to forecast the savings rate for the three years since the test statistics (see under 'Forecast') do not reject parameter stability. This is to be interpreted as conveying that the behaviour of the savings rate since 1991 is not egregious in light of the associated growth in real income.

Admittedly, the econometric analysis here is rudimentary and much remains to be done. For a start we should perhaps be estimating a system of equations and work with more sophisticated specifications. So the results must be seen as being indicative, no more. However, eyen while it may not constitute a complete explanation, the slowing down of the growth rate of the Indian economy since 1991 must be taken into account when evaluating the dip in the savings rate coincident with that date. In particular, it needs to be noted that it is the non-agricultural sector of the economy that has been affected

most, and there is the view [RBI 1982;46] that the marginal propensity to save is higher in this segment of the Indian economy. Industrial growth remained depressed for all the three post-reform years for which we have data on savings. In 1994-95 the industrial production rate has finally regained something like the average rate for the 1980s It would be interesting to see how the savings rate, in particular the household saving rate, performs in that year. The data are yet to be in.

As for the relationship of all this to the reform process and liberalisation in particular, it needs to be remembered that the period since 1991, especially the early years is also one that saw the institution of a true-blue stabilisation programme. Conventional stabilisation programmes lead to a slowing down of growth, widely agreed to be an inevitable consequence which some assert is a temporary phenomenon. Now, once you allow for the persistence of consumption, which must link savings to (real income) growth, the observed behaviour of the savings ratio in the Indian economy is neither difficult to explain, nor a matter to be reconciled against all odds with the liberalisation process.

I now return to a feature that I have referred to earlier. This is that the household saving in physical assets, being derived (as a residual) from data on gross domestic capital formation is actually equal to capital formation in the household sector. This feature has been used variously to comment upon the estimates of the savings rate in recent years in the Indian economy. For instance, as mentioned earlier on, Athukorala and Sen have referred to the, alleged, divergence in the household and corporate capital formation rates as suggestive of estimation bias. There is the view that this definition of saving has a tendency to inislead. Rakshit (1982, 1983) has argued that while it may be convenient for the RBI to estimate aggregate household saving in this way, the classification has no substantive content when it comes to the explanation of saving. Household savings in physical assets only refers to that part of household saving that has found its way into capital formation. The savings decision must be explained in the aggregate, as it were. This is a powerful argument indeed but not one that cannot be countered. Savings and investment decisions are indeed separate in advanced industrial economies. In fact, this is the foundation of Keynesian economics. However, it is entirely conceivable that in segments of the Indian economy these two fundamental decisions are vested in the same unit, the 'household' (Kurien (1972) terms these 'producer households'). If this is conceded, then some of the standard arguments advanced for why capital formation gets depressed during stabilisation and adjustment programmes now get a new lease of life. Since these are well known I do not develop the argument [Serven and Solimano 1993]. Nevertheless, it needs to be emphasised that the registered decline in household investment in 'plant and machinery' is indeed very high and remains an issue that requires special consideration. Data on capital formation by institution is given in Table 9. Recall that for hosueholds, capital formation equals savings in the form of physical assets.

In conclusion, I wish to point to one item of expenditure which has a bearing on the finding of a declining saving rate. This is the rising price of land in the Indian economy for about a decade now. When households invest in residential property the price of land is of course factored into the price of the property. Now, the commodity-flow method used by the CSO attempts to estimate the material investment in construction. Even when it does get right the value of such flow it, in full awareness of course, excludes the outlay towards the purchase of land. The point of this is to convey that it is not necessary to resort to arguments of incorrect measurement to understand the declining savings ratio in the Indian economy. Rising real estate prices may well be part of the explanation. Now it does not even matter that they may be under-reported in documentation of the transaction. This item. is just not captured in the estimates of capital formation. There is some reason to believe that a certain amount of external inflows that followed after the policy shifts since 1991 may have been directed into real estate. bidding-up the price of land in urban India.

#### VI Estimation of Household Saving in Financial Assets

I commence with a general comment on the methodology adopted for the estimation of household savings in India. As a concept, the saving of the household sector is the balancing item on the income and outlay account of the household and should equal the sector's current income over current expenditure. This is accepted in principle even by the C3O (1989). However, a direct estimate of household saving as the difference between income and expenditure is not available, and therefore, it must be estimated by deducting from the economywide figure for capital formation and financial saving, rispectively, the estimates of the same for the public and private corporate sectors. The implications of such a procedure for the available estimates of household savings in physical assets has been considered earlier on in this study. I now look at some of the implications as they may arise in the case of the estimation of financial savings.

A brief statement on the method of estimation of household saving in financial

assets is provided in the Report of the Working Group on Savings:

The household sector saving in the form of financial assets is estimated instrumentwise. The instruments of financial saving are: currency, net deposits, investment in shares and debentures issued by the corporate sector, net claims on government in the form of small savings, central and state government securities, and net increase in the claims of households in life insurance and provident funds. In respect of all of these, the basic information on year-end totals is obtained from the accounts of the financial institutions and government budgets (supplemented with special returns) and the estimated holdings of the private corporate sector and the public sector are deducted to arrive at the holdings of the household sector. Some of the instruments are presented in net form by making adjustments for the liabilities incurred by the household sector against the institutions in which those financial assets are held.

It was generally agreed that the data base for the estimation of financial saving was comparatively firm [RBI 1982:83. Note this observation].

EPWRF (1995) had made some observations regarding the estimation of saving in the Indian economy, all of which amount to the claim that household saving in financial assets may have been overestimated in the 1990s. The crucial observation concerns the very high financial inflow into the Indian economy following upon both the relaxation of curbs on foreign investment and the floating of the rupee more generally, at least on current account. I consider the arguments concerned.

EPWRF (1995) first focuses on the increased portfolio investment by financial companies. It is pointed out that under the present methodology a part of the increase in the domestic currency is automatically accounted as saving of the household sector. EPWRF (1995) wavers a little between giving prime importance to the argument that portfolio investment should be treated as foreign saving and the one that in the allocation of the increased currency consequent upon such inflows the use of outdated ratios tends to overestimate household saving. On the latter question, Athukorala and Sen (1995) point out correctly that, under the extant methodology, what results from the use of inappropriate ratios is only the overestimation of household saving (in currency) not aggregate financial saving in the Indian economy. That is, we may have unearthed a sort of allocation problem here, rather than a problem of the correct estimation of the volume of saving in the aggregate. This is clear in the CSO's statement of the methodology it adopts: "On the question of cash in hand, the Advisory Committee on National Accounts in its meeting held in June 1987 had suggested that the present procedure of estimating the currency with the households by deducting from the total currency the currency held by various institutional sectors may be examined. It had further suggested that a simple procedure of possibly taking a proportion of the total currency in circulation might serve the purpose. Accordingly the RBI, on the basis of past trends of currency holding of the household and non-household sectors, estimated this proportion to be 0.93 which has been used for estimating the currency holding of the households from 1985-86 onwards" [CSO 1989:220-21]. This more or less disposes of, given the concerns motivating this study, any real interest that we might have entertained via-a-vis the EPWRF's contention regarding the consequences of increased portfolio investment. Moreover, the focus on the extremely high inflows of 1993-94, even though EPWRF emphasises that in principle the problem exists in other years as well, does rob the argument of a more general appeal. The point is that the household saving rate in financial assets is (Table 21) almost as high in 1991-92 as it was in 1993-94 the year that the EPWRF has focused on [EPWRF 1995: Table 21]. However, the question of the appropriate treatment of portfolio investment is indeed important and the EPWRF (1995) is the only study to have raised this point. But there appears to be a bind. While the automatic treatment of such inflows as domestic savings is certainly inappropriate, the EPWRF's suggestion that it be treated as foreign saving because it goes to increase capital formation IEPWRF 1995:1031] is untenable because many foreign institutional investors buy scrips in the secondary market, and this does not lead to capital formation.

On the question of private transfers or 'foreign remittences on private account' EPWRF (1995) has a more complete argument. It deserves attention and I quote at length:

The nature of increases in foreign inward remittances on private account, including their sharp jump in rupee terms during the past three years due to a sizeable depreciation of the currency have been spelt out earlier. Such remittances are treated as unrequited transfers and included under the current account of the balance of payments (BoP). However, their treatment for national accounts purposes differs somewhat. In this regard, the UN System of National Accounts (SNA) lays down clear guidelines for dividing such transfers between capital transfers and unrequited current transfers, with capital transfers from the rest of the world constituting an independent source of finance for accumulation and current transfers as additions to the recipients' income account. According to the SNA, capital transfers are those grants which the recipient uses for financing accumulation; alternatively, the payer may consider that he is placing part of his saving at the disposal of the recipient. On both the counts such transfers should appear as part of capital finance. On the other hand, if the recipient utilises the grant to finance his consumption expenditure, the size of saving on the consolidated accounts of the recipient and the payer would be correspondingly reduced; such transfers then partake the character of current transfers. The main criteria adopted to distinguish capital transfers from unrequited current transfers are therefore the purposes for which the transfer is to be utilised, the basis and source of the payment, and the frequency with which the transfer occurs from the point of view of either the payer or the recipient (UN SNA, 1968, para 7.77, p 131).

In the Indian system of National Accounts Statistics (NAS), the CSO, considering the difficulties involved in classification, has opted for treating all transfer payments on private account as current transfers (and all on government account as capital transfers) [CSO 1989: 330]. It should be pointed out that considering the enormous size of private transfers now taking place, it is inadmissible to assume that all such private transfers are of a current nature intended for consumption purposes. First, if we have to be true to the UN SNA framework, it would be necessary to classify a part of such transfers as capital transfers flowing from savings of the nonresident Indians living abroad which are used for capital accumulation purposes in India. If such a presumption is accepted, the implication for household saving and investment estimation, and in turn, for the aggregate domestic saving and investment, is of a significant nature. Briefly, under such a dispensation, of the total private transfers indicated above, the part designated as capital transfers will have to be deducted from household saving in the form of financial assets and simultaneously added to the amount of capital inflow from abroad as they would represent that part of the saving of the rest of the world used as a source of finance for accumulation in the domestic economy [EPWRF 1995:1034].

The logic of the EPWRF argument is impeccable. The part of foreign inward remittances that goes into capital formation must be treated as foreign savings. Secondly, to assume that all such remittances go directly to augment domestic saving would indeed be wrong.

Two responses may be made to the EPWRF argument. The first, made by Athukorala and Sen (1995), provides a sort of empirical evaluation of its significance. It is that even if it is taken to be the case that remittances are fully translated into household financial saving, the "... increase in remittances could account for only about 0.7 percentage point increase in the average rate of household financial saving in 1991-92 and 1993-94 over the average level for the preceding three years [calculation based on Table 7 in EPWRF 1995" [Athukorala and Sen 1995:2189. I have treated the Athukorala-Sen estimate as correct].

argument has a bearing on the investigation of the measured decline in the household savings rate since 1991. This is that if we are to take the EPWRF's suggestion and treat the substantially increased foreign remittances since 1991-92 as evidence of repatriation for purposes of capital accumulation, then fluctuation in such remittances would not enter the household (financial) savings rate and this would rob the EPWRF (1995) argument that estimates of this rate for the 1990s is actually an overestimate<sup>2</sup> of much of its sting.

In this discussion I have not discussed sources of bias in the estimation of household saving that are of a perennial nature. I refer to the tendency to estimate year-end figures which had introduced the incentive for various forms of 'window-dressing' such as the bunching of transactions. Instead I have only considered those aspects of the methodology that have particular bearing on the behaviour of the savings rate in the years since 1991.

#### VII Postscript

It is customary in traditional econometric practice to test one's model against data from outside of the sample. In time-series analysis the terrain usually chosen is the post-sample period. I have in this study looked at the evidence for the three years following 1991 up to and including the year 1993-94. In this connection, the publication on February 2, 1996 of the Quick Estimates of national income, consumption expenditure, saving and capital formation for the year 1994-95 provides a research opportunity rather like that of an out-ofsample period test. Essentially, we would be interested in the relationship between the overall growth in the economy and the behaviour of the household savings rate during this year. Domestic saving as a percentage of GDP at market prices amounted to 24.4 per cent in 1994-95. The figure for household saving is 18.9 per cent. The growth rate of GDP was 6.3 per cent. Figures of the savings rate and of the rate of growth in previous years are to be found in Tables 1, 2 and 7, respectively. The contemporaneous rise in the household (and aggregate) savings rate and the growth in real income (GDP) is consistent with the explanation of the behaviour of the savings rate since 1991-92 that has been provided earlier on in this study. What lends particular credibility to the argument that short-run fluctuations in the savings rate are to be seen as resulting from a steady growth of consumption in the face of downward fluctuations in real income growth is that it is the component 'household' saving that fluctuates most and also, more importantly,

most crosery with the growth rate in the economy.<sup>3</sup>

It has not escaped my attention though

that the behaviour of the savings rate in 1992-93 is at odds with the argument attempted to be captured in the econometric model above, or more generally, the argument that the savings rate is related to the rate of growth. In 1992-93 the savings rate declines despite the improvement in the rate of growth [Tables 1 and 7] thus constituting some sort of a puzzle. In fact, it was this feature that had led the government of India to suggest that the methodology of estimation may be erroneous [Economic Survey 1994-95:3]. While the question of explaining the decline in the savings rate in that year remains, the reference to estimation bias may be a little rushed yet. There are at least four reasons to suggest this. First, recall that it was in April-May of 1992 that the financial scandal relating to the use of government securities came to light. It is entirely conceivable that this led to a certain cautiousness with regard to the forms of saving adopted by households. This is reflected in the very considerable decline in household saving in financial assets in 1992-93 [Table 2]. There was an across-the-board deflation of stock prices in that year. Secondly, in March 1992 the government of India liberalised the import of gold with likely consequences for the measured savings rate, as I have discussed above. Import of gold into the economy in the years 1990, 1991, 1992 and 1993, respectively, amounted to 506, 319, 2,46,378 and 3.489 in thousands of US dollars (International Trade Statistics Yearbook 1993, UN Statistical Office, New York). The surge in 1992 is extraordinary and unmistakable. (Of separate interest too is the quick response of the Indian economy to shifts in policy.) Third, in the first flush of its successful handling of the crisis of 1991 and, even more importantly, with the IMFprogramme no longer in place the government had slackened in its resolve to rein-in government spending. Public saving in that year declined [Table 1]. All three factors act on the savings rate independently of the rate of growth of income in the economy. Finally, in a return to the argument of the causal importance of growth we might point out that while it is the case that GDP, led by an exogenous improvement in agricultural production, turns around in 1992-93 the rate of growth of manufacturing remains a paltry 2.2 per cent [Table 7]. We are familiar with the argument that the marginal propensity to consume out of nonagricultural incomes may be higher than it is out of agricultural ones. So, while it is indeed the case that the behaviour of the savings rate in the year 1992-93 cannot be explained in terms of the growth in real income perfectly plausible explanations can be put forward, as they have been here.

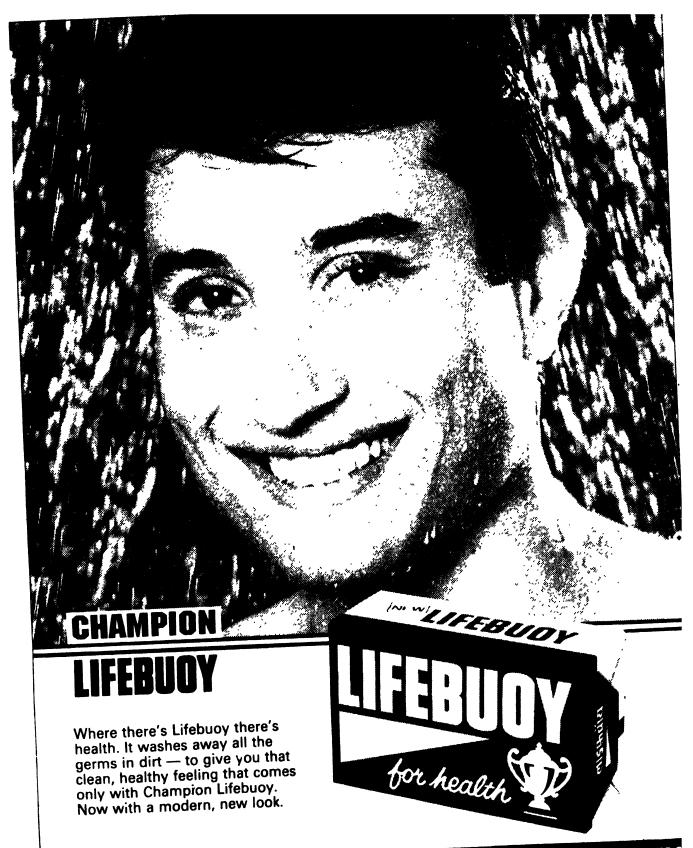

#### Notes

[I am grateful to Mridul Saggar and A Vasudevan of the Reserve Bank of India and Lant Pritchett of the World Bank. Errors, if any, can only be mine.]

- 1 This was written some weeks before the figures for 1994-95 were announced. See Section VII.
- 2 And, as a corrollary, that the actual decline in the household saving rate during this period is greater.
- 3 The figures for the savings rate of the public, private corporate and household sectors of the economy for the year 1994-95 are 1.7, 3.8 and 18.9 per cent, respectively. See CSO (1996). These figures may be read along with those in Table 1 and in conjunction with the figures on growth in Table 7

#### **Explaining Post-Reform Industrial Growth**

#### C P Chandrasekhar

A close scrutiny of the estimates of capital formation in the post-reform period shows that no linkage can be established between liberalisation, private investment and industrial growth. What liberalisation has done is to unleash a consumption boom, fuelled by a surge in consumer credit that has accompanied financial sector reform. Such a boom not only increases balance of payments vulnerability, but also offers, in terms of markets, only a once-for all boost that would exhaust itself unless some other stimuli ensure expansion of the home market for manufacturers.

AMONG the indicators chosen by advocates of the 'economic reform' of the 1990s as proof of its success, the growth in industrial production is the most persuasive. It is still true that the average rate of industrial growth (as measured by increases in the index of industrial production (IIP)) over the five post-reform years (1991/92-1995/96) is, at 7.4 per cent, below the 8.3 per cent recorded during the immediately preceding five-year period (1986/87-1990/91). However, an examination of annual growth rate figures suggest that they have risen almost consistently over the last five years, from 0.6 per cent in 1991-92 to 2.3 per cent in 1992-93, 6.0 per cent in 1993-94, 9.4 per cent in 1994-95 and 120 per cent in 1995-96 (Table 1). This stepwise return to annual rates similar to, or even better than, those which prevailed during the 1980s manufacturing boom has encouraged the view that after a short period of a stabilisationinduced decline in growth rates, manufacturing production is once again entering a phase of secular growth.

Needless to say, the more recent IIP estimates are still provisional. And, if 1993-94 is any indication, the official index of production sees rather volatile changes in the course of the routine revisions made to it from its 'provisional' to its 'final' form, rendering it a doubtful measure of the degree of buoyancy of manufacturing. When official spokesmen confidently quote 6.1 per cent as the rate of growth of manufacturing production in 1993-94, few remember that that figure is the culmination of a series of revisions. Thus, the Reserve Bank of India's Report on Currency and Finance, released towards the end of the calendar year 1994 had estimated the growth in the index of manufacturing production in 1993-94 at just 2.37 per cent. A few months later, the official Economic Survey from the finance ministry released just before the budget in February 1995 provided a revised estimate of 3.61 per, cent. Subsequently, that figure was revised thrice over, initially upwards to 6.1 per cent then to 5.6 per cent and finally again to the 6.1 per cent figure doing the rounds in official statements now. Such dramatic changes over relatively short periods of time do induce an element of scepticism about the veracity of the figures provided and therefore about the reported rate of growth.

This scepticism is compounded by an analysis of the sectors accounting for the revisions in the index, which have led to significant changes in the rate of growth of manufacturing in any period. A substantial part of the rise in the growth rate on account of the revisions of the 1993-94 manufacturing production index from 2.4 per cent to 6.1 per cent is due to revisions in just three sectors, viz, cotton textiles (resulting in a rise in its growth rate from 3.6 to 6.9 per cent),1 leather and fur products (6.1 to 8.8 per cent) and basic metal and alloy products (5.1 to 33.4 per cent). This concentration of the effects of the revision gives cause for concern because a few sectors, in any case, account for a dominant share of growth in particular years during the 1990s. Thus, rates at the two-digit level indicate that, in 1993-94, three (out of 17) sectors - beverages, jute, hemp and mesta products and basic metals and alloy products - recorded remarkably high rates of growth of 21 2, 18.6 and 33.4 per cent, respectively. On the other hand there were four - food, metal products, electrical machinery and 'others' - which registered a decline in the value of the index of production in that year. Thus one sector which 'benefited' from significant revisions in the index of production, namely, basic metals and alloy products itself would have, with a weight of 9.8 out of manufacturing's total of 77.11, helped the manufacturing sector notch up a growth rate of 4.2 per cent.2

This experience is telling because significant differentials in growth performance at the two-digit level persisted in subsequent years as well. Thus, in 1994-95 five out of 17 sectors (chemicals, metal products, non-electrical machinery and machine tools, electrical machinery and appliances, and, transport equipment), which accounted for a third of manufacturing's weight in the general index, could account for two-thirds of the growth of the manufacturing sector

These sharp variations in the rate of growth across sectors, or the lack of a 'synchronised recovery', tend to reinforce doubts about the reliability of the index. They also suggest that generalised or omnibus stimuli to the recovery like government expenditure or a surge in public and private investment, are either being counteracted by other factors (like import liberalisation) with greater effect in specific sectors or are less significant as explanations for growth in the post-reform period. In fact, post-reform industrial growth trends as reflected in movements in the IIP are puzzling for three reasons. First, while the industrial 'recovery' in 1993-94 was accompanied by a sharp rise in the fiscal deficit in the central budget to 7.5 per cent of GDP, the subsequent two years have actually seen a reduction in that deficit to 6 9 and 5 9 per cent, respectively 3 Inasmuch as deficit spending by the government directly and indirectly (through its income effects) spurs industrial demand, the high rate of industrial growth in years of relatively lower deficits is noteworthy. Second, the years of high growth have been ones in which the government has vigorously pursued a strategy of import liberalisation and customs tariff reduction, resulting in a large inflow of imported manufactures into the Indian market. To the extent that such imports displaced local production catering to domestic demand, it should have slowed down the growth in industrial output Finally, in recent years real interest rates have risen to extremely high levels by historical and international standards. This should have discouraged industrial investment and therefore the growth of domestic production.

The significance of these factors that should have contributed to slower industrial growth airing the 1990s needs closer scrutiny. In the discussion surrounding the factors explaining the sharp slow-down in industrial growth in the immediate post-reform years (1991-92 and 1992-93), five factors were assumed to drive industrial growth. These factors had emerged as significant in explaining patterns of the second episode of post. Independence industrial growth starting

around the mid-17/05. Phist, capital formation in the public and private sectors provides a stimulus for industrial growth in the form of both the direct demand or purchases that such expenditures involve, and the indirect demand resulting from incomes generated by investments. Second, the current expenditure of the government also serves as a demand stimulus and therefore as a spur to industrial growth. Third, the relaxation of government controls on imports during the late 1970s and the 1980s can have contrary effects on industrial growth. This has been seen by some as having stimulated industrial growth because of enhanced access to capital goods. intermediates and components, and by others as having adversely affected manufacturing production because of the 'deindustrialising' effect of increase in manufactured imports. Fourth, the performance of the agricultural sector, being a source of demand as well as of supply of crucial agro-industry inputs for the industrial sector, affects industrial growth from the demand and supply sides. Finally, some have also stressed the role of access to finance and the cost of such finance, which could prove a supply-side constraint on industrial growth.

An examination of the relative significance of these factors as stimuli for the growth of manufacturing production during the years 1975-92, and therefore as explanations for the immediate post-reform recession yields some interesting conclusions. To start with, the analysis suggests that agricultural output and prices, as well as credit variables like the volume of bank credit to the commercial sector or interest rates, have little proximate association with changes in manufacturing production during this period and are therefore inadequate as explanatory variables for rate of growth of manufacturing output. Thus, although agricultural output declined in 1979-80, 1982-83 and 1991-92 which were all years when manufacturing growth dipped, manufacturing continued to have high growth during the period 1984 through 1987 when there was negligible agricultural growth. In any case, what is important about the early 1990s recession was that it was sustained through a year of excellent harvests in 1992-93. Similarly, while there was a marked fall in the growth of credit after 1988-89, the credit squeeze came at least a year before the onset of recession in 1991-92 and the latter was not reversed in 1992-93 despite credit increasing by 5 per cent in real terms. Moreover, although real interest rates were on the rise since 1989-90, those rates were during 1991-93 no higher (after allowing for inflation) than those prevailing between 1981 and 1987, when manufacturing sector growth was rapid. And the general argument which attributed the recession to a supply-side financial squeeze is even less tenable when account is taken of the fact that the share prices rose sharply starting 1991-92 and record amounts of capital were raised in primary issues.

Thus, although they are plausible determinants of manufacturing growth in general, agriculture and rinance do not seem to have been major factors behind the 1990s recession. However, since it can be misleading to consider possible determinants one-by-one, all the variables discussed above were introduced simultaneously into a regression exercise, along with other variables, to explain manufacturing growth between 1975-76 and 1992-93. Neither agriculture nor the financial variables were found to be significant. On the other hand, the level and rate of total capital formation, government expenditure and import competition did emerge as significant explanatory variables.4 As suggested by the statistical results the fitted equation quite closely approximated the actual values, and. in particular, predicted accurately the onset of the recession in 1991 and the continuing sluggishness of manufacturing thereafter, although the model itself used data from the pre-recession period to estimate the parameters.

What the estimation indicates is that the dominating influence on industrial growth in the period after the mid-1970s was the rate of change of real gross fixed investment in the private and public sectors. Since investment in any particular year cannot be expected to contribute to output through higher capacity creation in that year itself, this suggests that the principal factor driving industrial growth was the rate of change of investment demand. This feature also helps cement a relation between the level of total real fixed capital formation in any particular year and the rate o growth of manufacturing production in the subsequent year. However, even in 1991-92, when 'import compression' was held to account for the recession, the

ievei or manufactured imports in real terms was less important as a factor explaining the industrial downturn than the cutback in gross fixed investment. In fact, when we look at the relation between the rates of growth of manufacturing production and those of manufactured imports, we find that while in general the two move in tandem, there are instances, such as in 1984-85 and 1987-88. when high manufacturing growth continued although import compression was greater than in 1991-92. Not surprisingly, the evidence suggests that during the early 1990s it was not import reduction that was driving the recession, but the reduction in output that was dampening the rate of expansion of imports. That is, while periods of decline in manufacturing production do slow down import growth, liberal imports can and do rob the domestic manufacturing sector of the full benefits of any increase in the home market.

In fact, this asymmetric relationship with the rate of change of manufacturing output appears to be true of real total central government expenditure as well. Clearly, the increase in such expenditure has provided a stimulus to industrial growth, since periods of rising government expenditure are also ones in which the rate of growth of manufacturing output is high. However, while real central government expenditure does fall to an extent in 1979-80 and tapers off during the early 1990s because of the enforced cut in the central government's fiscal deficit, the extent of the recession appears to be far more severe than warranted by the trend in real government expenditure. The model suggests that the demand impetus provided to manufacturing by government revenue expenditure is less than that provided by investment expenditure, whether private or public, although public investment clearly has a greater demand impact on manufacturing sector than private investment.

All this makes clear that it was the

deceleration in the rate of change of gross fixed capital formation in the public and private sectors that was primarily responsible for the early 1990s recession. The question that arises is: what factors accounted for the deceleration in real investment growth? To those acquainted with the effects of IMF-type 'macro-economic adjustment' elsewhere in the developing world, the deceleration in productive investment should not come as a surprise. As a multi-country research project co-ordinated by economists in the Policy and Research Division of the World Bank<sup>3</sup> suggests, there are a number of elements of such an adjustment package that affect capital formation adversely. To start with, a principal component of adjustment is a reduction in public expenditure. With a pre-existing administrative apparatus and a stock of debt which make a reduction in government consumption spending and interest outflows difficult to ensure, public expenditure cuts more often than not result in a cutback in capital formation in the public sector. Hence, if adjustment is not to result in an overall deceleration in investment, capital formation in the private sector must increase, if is to do more than neutralise the brake on public investment.

Whether private investment will step in to take on the role of public investment depends on whether there is any pronounced positive association between public and private investments. Many economists have argued for such an association in the Indian economy.6 Even the studies undertaken as part of the World Bank project mentioned above found "strong complementarities between public and private investment for a panel of Latin American, African and East Asian countries." The significance of this evidence needs to be noted. There are many who have argued that public sector capital formation, financed with public sector deficits, constitutes a draft on private savings and therefore pushes up interest rates and reduces private sector access to credit. What the evidence suggests is that, even if true, the consequent positive effect of reduced public expenditure on private investment is overwhelmed by the adverse impact of declining public capital formation on such investment.

A preliminary exercise provided more detailed evidence on the influences explaining private investment trends in India. Private investment consists of two components: that undertaken by the 'household sector' which also includes small business; and that undertaken by the "corporate sector". Needless to say, the dominant influences on these need not be the same. A detailed statistical analysis that took account of all the variables mentioned above for the 15-year period 1977 to 1992 did find that the principal determinants of household and

corporate investments varied to an extent.7

In the case of household capital formation. the real interest rate appeared to have a strong negative effect while fixed capital formation in the government sector had a weak positive effect, although the latter relationship was better when lagged by one year. In the case of corporate fixed investment, fixed capital formation in the public sector had a strong positive effect while relative prices which can affect industrial profitability (such as the relative price of agricultural products with respect to manufactured goods or the real effective exchange rate) also exerted their influence in the expected manner. Thus, in both cases, fixed capital formation by the government was a significant determinant, but as expected the responsiveness of fixed capital formation in the household sector to this was far less than in the case of the corporate sector. What is more interesting is that while the level of the interest rate was significantly inversely related to capital formation in the household sector, it was not a significant negative influence on fixed capital formation in the corporate sector.

All of this points to the strong complementarity between public investment and private investment in the Indian economy. Rather than 'crowd out' private investment by its draft on private savings, public investment through its demand-generating effects and its provision of crucial infrastructural support, 'crowds in' private investment. Hence, to the extent that a macroeconomic adjustment programme involves a reduction in the rate of growth of real public investment (as part of the effort to reduce the fiscal deficit), private investment is also likely to be depressed. This means

that unless there is some major structural shift in the factors that drive private investment, such investment is unlikely to compensate for the reduction in public capital formation that adjustment involves.

The advocates of reform in India did expect such a structural shift. Thus, even when industrial growth was still low, the official Economic Survey argued that "structural reforms have had a positive impact on the investment climate in the country" and that "the conventional indicators suggest that the investment climate has remained buoyant"." Clearly, the impression was that even if in the immediate aftermath of adjustment in private investment did not increase to the requisite degree, in course of time the 'animal spirits' of private entrepreneurs would respond adequately to the incentives that the liberalisation associated with adjustment involves. Those incentives came from various elements of the liberalisation programme aimed at facilitating private investment: the dismantling of government controls on capacity creation, production and pricing; improved access to imported capital equipment, raw materials and intermediates; and easier possibilities of technical and financial collaboration with foreign entrepreneurs.

For these advocates of reform, the fact that despite several dampening influences, India witnessed an industrial 'boom' of sorts implicitly suggests that liberalisation has permitted private industrial investment to break with its many-sided dependence on public investment, and register autonomous increases so long as access to finance is ensured to entrepreneurs. According to them, with stock market and capital market reforms and liberalised rules with regard to foreign

apital entry having ensured such access to inance, the 'animal spirits' of entrepreneurs vere significant enough to set off a wave of nvestment that helps lift the rate of industrial rowth. Capital formation estimates appear o partially corroborate that case. Thus, with overnment capital formation stagnating, vhile agricultural product prices were rising nd the real exchange rate depreciating in he early 1990s, capital formation in the rivate corporate sector should have been dversely affected (Table 2). However, CSO igures suggest that capital formation in he private sector (at 1980-81 prices) rose rom Rs 12,032 crore in 1990-91 to ls 15,329 crore in 1991-92, Rs 18,442 rore in 1992-93 and stood at Rs 18,267 rore in 1993-94. Relative to GDP, this mounted to a rise from 4.6 per cent in 990-91 to 5.9 per cent in 1991-92 and 6.7 er cent in 1992-93 (Table 3). The 1993-94 igure stood at 6.1 per cent. In the case of ousehold capital formation, with governnent capital formation stagnating between 990-91 and 1993-94 while interest rates emained high, this segment of private capital ormation should have also been dampened. Here, the evidence indicates that it was. At constant 1980-81 prices it fell from ls 23,651 crore in 1990-91 (11.3 per cent of GDP), to Rs 15,329 crore in 1991 92 (7.8 er cent), rose marginally to Rs 16,084 crore n 1992-93 (7.7 per cent) and then fell again o Rs 14,042 crore in 1993-94 (6.6 per cent). Thus, the 'corporatisation' of private capital ormation until 1993-94 seems to tally with he expected link between liberalisation, private corporate investment and industrial growth, especially since public capital ormation was declining relative to GDP.

However, there are two aspects of these estimates which conflict with that generalisation. First, the revival of private orporate investment occurred during 1990-91 to 1992-93, which is well before he post-reform industrial recovery. Second, elative to GDP the decline in household capital formation (3.6 percentage points) was much more than the increase in private sector capital formation (2.1 percentage points), so that overall private capital formation has been on the decline. Unfortunately, revised estimates of capital formation are not available for the period after 1993-94 and large revisions of the CSO's 'Quick Estimates' are the norm, making them an inadequate basis for judgment. However, the Quick Estimates for 1994-95 point to a significant increase in real capital formation in all sectors, amounting to 13 per cent in the case of the public sector, 16 per cent in the private corporate sector and 34 per cent in the household sector. If acceptable, they suggest that the break with the earlier period appears more generalised in that year.

The CSO's aggregate figures on capital formation seem to support this argument on the surface. In the immediate post-reform years, gross capital formation in the economy fell sharply from 27.1 per cent of GDP in 1990-91 to 23.6 per cent in 1991-92, 22 per cent in 1992-93, 21.6 per cent in 1993-94 and then rose sharply to 25.2 per cent according to the quick estimates for 1994-95. It is true that capital formation in the private corporate sector rose from 4.6 per cent of GDP in 1990-91 to 5.9 per cent in 1991-92 and 6.7 per cent in 1992-93 and after a marginal fall to 6.1 per cent in 1993-94, settled at 6.6 per cent of GDP in 1994-95. However, capital formation in the household sector, which fell sharply from 11.3 per cent in 1990-91 to 7.8 per cent in 1991-92, 7.7 per cent in 1992-93 and 6.6 per cent in 1993-94, rose back to 7.8 per cent in 1994-95. Thus, while the improvement in corporate capital formation was partly neutralised by the decline in household sector capital formation in the early 1990s, it was supported by it in 1994-95, when the household sector contributed quite significantly to the rise in overall capital formation. If the 1994-95 trend is combined with the fact that public expenditure rose sharply in 1993-94 resulting in the highest post-reform deficit of 7.5 per cent of GDP, an explanation for the return to higher rates of growth appears readily available. Public expenditure and private capital formation together seem to underlie industrial buoyancy.

However, there is still one reason for scepticism. Relative to GDP private corporate capital formation rose only marginally between 1993-94 and 1994-95 from 6.1 per cent of GDP to 6.6 per cent, so that the

overall increase in capital formation from 21.6 per cent in 1993-94 to 25.2 per cent in 1994-95 was due largely to a 1.2 percentage points increase in the ratio of capital formation in the household sector to GDP and a 1.8 percentage points increase in the case of the 'errors and omissions' category. These trends in the sectoral composition of capital formation, especially the unusually large 34 per cent increase in household sector capital formation, call for closer scrutiny of the CSO's figures.

Central to savings and investment estimates in India is the idea that domestic investment must always identically equal the domestic savings plus net capital inflows from abroad. Net capital inflows, which equal the deficit on the current external account are obtained from balance of payments statistics. In a division of responsibility suggested by the Raj Committee on Savings, the CSO is primarily responsible for estimates on the investment side and the RBI for estimates on the savings side. The CSO follows a product-flow approach in estimating investment by assets. Overall investment is taken to be the sum of 'investment goods' (machinery, construction and inventories) available in the economy either based on domestic production or through net imports, which gives the apparent consumption of such investment goods. This global figure is supplemented by estimates of corporate investment from company balance sheet data and of public investment from budget data. The difference between the overall investment figure and the total of private corporate and public sector investment is the residual that is treated as being the investment in physical assets by the household sector

Any errors in estimating the overall level of investment in the economy or in the public and private corporate sector components therefore affect the estimated household investment in physical assets.

On the savings side, public and private corporate sector savings are once again estimated from budget and balance sheet data. Household savings are estimated in two parts; one consisting of household saving in the form of physical assets, which is nothing but the residual obtained on the investment side as described above, and, the other of household financial savings, obtained from data on the assets and liabilities of the financial sector, adjusted for outstanding positions with the public and private corporate sector. Given the need to satisfy the investment savings-identity, any excess of domestic savings plus net external capital inflows over the CSO's investment estimate is added on to the capital formation figure under the head 'errors and omissions'. It should be clear that any overestimation of the 'residual' in the form of household physical savings, inflates the overall level of savings, and therefore the estimate of capital formation 'adjusted' for errors and omissions.

This structure of estimation suggests that when scrutinising capital formation estimates we have to look, in particular, at three possibilities. First, that there is no error in the global estimate of investment, which by inflating the 'residual' estimate of household investment in physical assets increases household savings as well. Second, that there is no inflation of household financial savings which is calculated as a residual from data on the assets and liabilities of the financial sector. And, third, that these two errors together do not inflate the 'errors and omissions' item in the 'adjusted' capital formation estimates.

Unfortunately, on all these counts there seems to be reason to doubt the veracity of the investment and savings figures in 1994-95, which support the case for a sharp revival in capital formation during the later reform years. Consider the overall investment figure, for example. In 1994-95, when capital formation as a proportion of GDP rose quite sharply, capital formation by the household sector in the form of machinery and equipment rose by 59 per cent. This, in that year, amounted to 22 70 per cent of the increase in total capital formation. As a result, the share of the household sector in purchases of machinery and equipment is shown to have risen from 12 per cent in 1993-94 to 16 per cent in 1994-95. This implies that the estimate of total purchases of machinery and equipment rose much more. than that which can be directly attributable to the public and private corporate sectors, resulting in a noticeable increase in physical asset creation by the household sector.

Whether this increase is acceptable or not depends on two factors: whether the aggregate estimate of machinery and equipment purchases is reliable; and whether the direct estimates of capital formation of the public and private sectors is valid: However, from the point of view of the aggregate capital formation estimate 'unadjusted' for errors and omissions, the latter is not a problem, since it would merely attribute to the household sector, what might rightfully belong to the other sectors. However, if the aggregate estimate itself is questionable, then the residual, large increase being attributed to the household sector may be an overestimate. There is reason to believe that this is what has actually happened in 1994-95.

One reason why capital formation in the form of machinery and equipment has gone up significantly in 1994-95, by as much as 18 per cent in constant price and 29 per cent in current price terms, is because that was a year in which both domestic production and imports of capital equipment went up sharply. Unlike 1992-93 and 1993-94, when production of capital goods fell while imports rose by more than 20 per cent a year because of liberalisation, in 1994-95 production rose by 24 per cent when imports rose by 26.1 per cent.10 That is contrary to the view that prevailed during much of the post-1985 liberalisation that increases in capital goods imports adversely affect production in the domestic capital goods sector, 1994-95 seems to suggest not merely that capital formation rose sharply, but also that it benefited both the domestic industry and international firms.

There is, however, a major change which has occurred in the period of accelerated

liberalisation since 1991. Because of the liberalisation of trade and foreign investment rules, many domestic and international manufacturers have chosen to set up capacities in India, separately or in collaboration, to assemble a range of commodities varying from 'electrical machinery' - which because of classification problems is often a euphemism for consumer durables of various kinds - to automobiles. To assemble these commodities, which are by their very nature import-intensive, imports, even of semi- or completelyknocked down kits, from the a foreign company or its third-country subsidiary, are resorted to. These imports, of machines and components, get recorded as capital goods imports in the form of either complete equipment or parts. Since domestic assembly based on such imports, is accompanied by sale at relatively high margins of the final product, which is also a capital good, the domestic value added associated with such activity also tends to be high. And, in any case, the value of domestic production, or domestic output, would include not merely the value added component, but the value of imported inputs as well. That is, a change in the nature of the domestic capital goods industry, encourages a tendency for imports and domestic production of this category of goods to rise simultaneously. If in these circumstances the methodology of using both imports and domestic production as 'independent' indicators of capital goods demand is used, there would be a definite tendency towards double counting, when overall purchases are estimated.

Interestingly, 1994/95 is the first year in which the trend towards a simultaneous increase in imports and domestic production

Source. Same as Table 4.

has affected the numbers. This is possibly explained by the fact that, after a year when production recovered from its 1991-92 and 1992-93 slump, this was the year when we had seen a revival in industrial growth. It must be noted that the pick up in capital goods production is accounted in large part by the segment 'electrical machinery and parts', which, besides automobiles, is one in which the tendency towards new international alliances is most visible, partially corroborating the case for double counting. Unfortunately, neither does the category capital goods in imports data correspond with that in production data, nor do we yet have access to commodity group-wise information on capital goods imports. However, there are strong reasons to believe that when the data becomes available the argument on double counting would be corroborated.

, If it is, then the 'residual' investment in physical assets in the household sector would prove an overestimate. To that extent the figures quoted by the CSO suggesting an increase in the rate of saving and investment in the economy, while in keeping with the CSO's methodology, would be the result of an overestimation that calls for correction. If and when corrected, the figures may show that the improvement in saving propensities or investment rates in the economy were not that significant.

The second area of doubt regarding the investment and savings estimates relate to the estimates of household financial savings. Household financial savings are estimated by the RBI using the data on holdings of individual financial instruments, with annual savings being the addition to total financial assets net of all financial liabilities. In 1994-95, such savings accounted for a significant part of a 3 percentage points increase in the savings rate from 21.4 per cent in 1993-94 to 24.4 per cent. Underlying this contribution was the fact that, despite signs of a decline in life insurance, provident funds and units, household financial savings are reported to have risen relative to GDP because of a steep increase in bank deposits from Rs 29,220 erore (or 3.6 per cent of GDP) to Rs 57,426 crore (or 6.1 per cent of GDP). This implies an increase in total household deposits (bank and non-bank) trom Rs 37,359 crore in 1993-94 to Rs 65,782 crore in 1994-95. The RBI's Report on Currency and Finance, 1994-95 reproduces these figures.

Interestingly, however, the RBI's Annual Report for 1994-95 released earlier had shown that household deposits had risen from Rs 37,329 crore in 1993-94 to only Rs 52,434 crore in 1994-95. To many observers this 25 per cent difference of more than Rs 13,000 crore (or 1.4 per cent of GDP) between the Annual Report figures

and those finally used by the CSO was a puzzle. It subsequently emerged that part of the increase has occurred because the 'revised' figures for 1994-95 are based on data for 27 fortnights while that for 1993-94 was based on data for 26 fortnights as should be the case. As the Economic and Political Weekly, which first reported this discrepancy argued: "It is obviously wrong to take data for an unequal number of fortnights in the different years as this would distort savings trends."11 When this distortion is corrected. not only do the savings rate decline, but so do the "errors and omissions" item in adjusted capital formation estimates, for reasons cited above.

This leads to the last point on the capital formation figures for 1994-95. If, as has been argued above, there is strong likelihood of an overestimation of both 'household savings in physical assets' and household financial savings, there should be a substantial degree of discrepancy between the estimates of savings and of unadjusted investment, resulting in a large 'errors and omissions' figure in the adjusted capital formation estimates. As expected, the 'errors and omissions' category in 1994-95 amounts to 2.1 per cent of GDP, up from just 0.3 per cent in 1993-94. This increase accounts for 50 per cent of the increase in the capital formation rate in 1994/95.

Thus, there are adequate grounds to believe that a major adjustment of the 1994-95 capital formation figures is likely, which may contradict the claim of a revival of investment and in all probability point to the persistence of a declining trend. Among the many macroeconomic indicators the Government has put together in Economic Survey 1995-96 to support its propagandist overview of five years of 'reform', are the quick estimates of savings and investment recently released by the Central Statistical Organisation (CSO). The above discussion suggests that not only has there been no such revival in investment but also that the stagnation in private corporate investment after 1992-93 works against whatever remains of the 'animal spirits' argument

This of course leaves unexplained the evidence of industrial recovery provided by the indices of industrial production. It can be argued that liberalisation, combined with

devaluation, has resulted in an increase in manufacturing production directed towards export markets, especially from the small and even unorganised manufacturing sectors This explanation is supported by the evidence that the value of exports in dollar terms has recorded a turnaround and that much of the expansion in manufactured export production is attributable to the small and unorganised sectors. The difficulty here is that net exports have in all probability declined, since liberalisation has also resulted in a share increase in capital goods imports. So while exports might provide sectoral explanations of growth, the overall effect of liberalisation on industrial production would in all likelihood have been adverse.

We therefore need to look elsewhere for features of liberalisation that spur manufacturing production. Viewed from the supply-side there is one reason why it should It has been known for long that one consequence of the complex of importsubstitution policies pursued by India till the mid-1980s was the pent-up demand for a range of manufactured goods, including specific brands of such goods. Knowledge of these could be acquired by consumers from the international market, but the products themselves could either not be acquired within India or acquired only at prohibitive costs. Liberalisation of the kinpursued in India, which frees access to intermediates, components and capital goods while protecting most end-products, as welas reduces tariffs substantially, allows for the domestic production/assembly and sale of these commodities in a relatively shor span of time. This occurs at two levels: first by relatively small firms that combine chear imports and domestic parts to service wha is not always correctly described as the 'grey market'; and second, by larger firms, very often in collaboration with international producers with a well-cultivated brand image

While such products do have a ready market, they would not contribute to a ne addition in domestic production if they displace similar or other products in the consumer's basket of purchases. Thus if the availability of new goods is to spur growth it must be accompanied by a net accretion to demand after accounting for the displacement of previously available 'substitutes'

Source: Same as Table 5

In the short run such net additions to demand can be financed either with the flow of hitherto unaccounted incomes into the market for goods, or with an element of dissaving reflected by reduced financial savings, or through increased recourse to consumer credit. There is reason to believe that in much of urban India and some parts of rural India, such a tendency is underway, driven by easy access to consumer credit.

It has been argued above that a liberalisation-induced rise in imports of knocked-down components for capital goods of various kinds, especially items like automobiles and electronic goods, can result in an overestimation of aggregate investment through a form of double counting. The problem, however, does not end here. The financial savings of the household sector consist of the addition to its holding of different kinds of financial instruments net of the increase in its financial liabilities. These financial liabilities take the form of loans and advances obtained from commercial banks and from the rest of the financial sector. An interesting feature in recent times has been the consumer finance boom, which on the one hand increases the financial liabilities of the household sector, and on the other increases its purchases of precisely those commodities that contribute to the 'double-counting' error that exaggerates the household physical savings spoken of above.

It could be argued in response to this argument that the real growth has been in household financial savings rather than physical savings. Through much of the 1980s physical savings exceeded financial savings, accounting for more than 60 per cent of the total in 1980-81, more than 51 per cent in 1985-86 and more than 55 per cent in 1990-91. However, in 1993-94 physical savings contributed just around 38 per cent of total household savings, and in 1994-95 it accounted for just over 41 per cent. <sup>12</sup> Thus, one feature of liberalisation has been a sharp rise in household financial savings, which involves no double counting.

The reasons for this trend appear to be an increase in investments in financial instruments other than bank deposits, such as life insurance, provident funds and pensions, on the one hand, and shares and debentures, on the other (Table 4). Financial liberalisation has meant both an element of disintermediation with banks losing their role as major channels for financial savings as well as a rise in financial savings by households. However, there are two features of household financial behaviour which are missed out in this characterisation. First, the financial portfolio of households is quite volatile. There was a hike in the interest rates on bank deposits in response to the diversification away from deposits. This, combined with the slump in stock markets in 1994-95, increased bank deposits by households sharply in 1994-95, with their share in gross household financial savings rising from 29.8 per cent in 1993-94 to 42.4 per cent in 1994-95. The 1994-95 share of bank deposits is higher than that in 1985-86. Second, while gross financial savings of households rose sharply (Table 6) from 10.7 per cent of GDP in 1992-93 to 14.3 per cent in 1994-95, net financial savings after rising between 1992-93 and 1993-94 from 8.4 per cent in 1992-93 to 10.8 per cent in 1993-94, stagnated in 1994-95. This was because the financial liabilities of the household sector, having fallen from Rs 16,395 crore in 1992-93 to Rs 11,995 crore in 1993-94, rose sharply to Rs 30,046 crore in 1994-95 (Table 5). Much of this increase was because of huge increase in bank advances to the household sector.

This aspect of the financial behaviour of the household sector is also related to financial liberalisation. Banks, which are being forced to offer higher interest on deposits given the relative returns of other assets, and are now also partially freed from constraints on their lending, are opting for consumer finance which offers much higher spreads than other forms of lending. Flush with funds because of the rise in deposits and concessions provided by the government, banks increased their lending by 28.7 per cent in 1994-95 to Rs 47,143 crore, as compared with an 8.2 per cent increase to Rs 12,346 crore in 1993-94. Not surprisingly, this increase was all due to non-food credit, with the growth in food-credit being lower at 12.5 per cent in 1994-95 as compared with 61.8 per cent in 1993-94. That consumer credit was an important contributor to non-food credit growth is indicated by the fact that scheduled banks' lending to sectors 'other' than agriculture, small-scale industries, other priority sectors, medium and large industry and the wholesale trade, rose by Rs 9,232 crore in 1994-95 as compared with just Rs 1,916 crore in 1993-94. In addition, there has been a phenomenal growth of nonbank financial companies in the postliberalisation period to an extent that there is now no real RBI monitoring over these companies, which have become a major source of consumer finance.

Thus, if the household sector has been buying more financial instruments, it has been borrowing more as well. In the event, there has been a dissociation between the gross financial investments by the household sector and its actual net financial savings, even according to the RBI accounts. This means that unless this much increased household borrowing was entirely for purposes of carrying out physical investment, the overall savings rate could be stagnant,

 notwithstanding the rise in household, gross financial savings. One can of course take the official figures at face value and conclude that there was indeed a massive increase in physical investment by the household sector. and the higher household debt was entirely to finance such investment. But given the overwhelming evidence of a hefty liberalisation-induced increase in debtfinanced purchases of consumer durables of various kinds, there is an alternative explanation. In a liberalised regime, where imported components are used to manufacture consumer durables which are then marketed with the provision of liberal consumer credit, financial dealings by households conceal a consumption trenc which aggravates the problem of double counting of household physical savings.

Consumer finance is provided precisely for those commodities - automobiles electronic goods, personal computers - which because of classification problems get registered as capital goods and in whose case the import-intensity of domestic production is extremely high. These are precisely the commodities which contributed to both the simultaneous rise in capital goods imports and the domestic production of capital goods For reasons mentioned earlier, the rise in the consumption and domestic production of such commodities increases the doublecounting error in product-flow estimates of total investment and therefore in ar overestimate of the residually calculated household saving in the form of physica assets. Put simply, the changed financia behaviour of households, which results in a stagnation in financial savings in a year in which financial investments rise, also results in a greater overestimation o household saving in the form of physica assets.

The implication of this is that though capital formation figures partially suppor the argument of an investment-led boom what is actually occurring is a consumption led boom which because of estimation problems shows up on the investment side This process of course is limited by two factors: first, the fact that credit of this kind can be provided only for durables with some resale value; and, second, by the level to which the overhang of credit can proceed before defaults become routine. Thus, the rapid growth in 'new markets' of this kind is bound to exhaust itself, just as the 'once for-all' market that import substitution initially provides did. This would be true for one other reason; consumption spending of the kind unleashed by liberalisation would have limited multiplier effects in the domestic economy given the high import intensity and low employment intensity characteristic of the production of sucl commodities.

To conclude, in the implicit debate on the relative role of 'animal spirits' and creditfuelled consumption in explaining the paradoxical recovery of industrial growth in post-reform India, the corporatisation of private investment and the recent evidence of a sharp rise in aggregate savings and investment have provided support to those who argue for a link between liberalisation. private investment and industrial growth. However, close scrutiny of capital formation estimates indicates that no such linkage can be established. What liberalisation has done is to unleash a consumption boom, fuelled by the consumer credit surge that accompanies financial sector reform. Such a boom not only increases balance of payments vulnerability if it is not accompanied by rapid export growth, but also offers in terms of markets only a oncefor-all market that would exhaust itself unless some other stimuli ensure an expansion of the home market for manufactures

#### **Notes**

- 1 The revisions in the case of textiles were over and above a revision in the index carried out inearly 1994 which had the effect of increasing the estimated output of this sector during April-December 1993 by over 10 per cent compared to that published in December 1993. Refer C P Chandrasekhar and Abhijit Sen, 'Industrial Recession and Prospect of Industrial Recovery', Macroscan, Business Line, February 3, 1994.
- 2 Figures are computed from data in Reserve Bank of India, Report on Currency and Finance, Mumbai, 1996.
- 3 Government of India, Ministry of Finance, Budgetata Glance, 1996/97, Budget Division, MOF, July 1996
- 4 The regression exercise which seeks an explanation for changes in the rate of growth of manufacturing production had as its determining variables the rate of change total gross fixed capital formation and the lagged level of total fixed capital formation, the level of total central government expenditure, the level of manufactured imports, and the lagged level of the index of industrial production, which captures the persistence over more than one period of the effects of the other determining variables. To avoid dimensional problems logarithmic values of absolute real values had been taken in the analysis. The estimated equation was of the form:
  - $Y = -2.05 + 0.59X_1 + 0.26X_2 0.06X_3 + 0.36X_4 0.58X_5$
  - Y = Rate of change of index of industrial production for manufacturing
  - X<sub>1</sub> = Rate of change of real gross fixed capital formation
  - X<sub>2</sub> = Log of real total central government expenditure
  - X<sub>1</sub> = Log of real value of manufactured imports
  - X<sub>4</sub> = Lagged value of log of real total gross fixed capital formation
  - X<sub>5</sub> = Lagged value of log of index of industrial production for manufacturing

- The R-squared value was 0.85. All variables were significant at less than 5 per cent level. The Durbin-Watson Statistic was 2.78. CPChandrasekharand Abhijit Sen, 'Industrial Recession and Prospect of Industrial Recovery', Macroscan, Business Line, February 3, 1994.

#### ESSAY COMPETITION ON THE OCCASION OF WORLD FOOD SUMMIT 1996

It gives us great pleasure to announce an all-India Essay competition (sponsored by the Ministry of Food, Government of India) on the occasion of the World Food Summit on the following topics.

- (1) Food Security: India's Quest For Self-Reliance in Food.
- (2) Fight Against Hunger.
- (3) Food Security in a Borderless World.

Original essay on any one of the above topics should be based on personal study/research/experience of the competitors and should be written in English. The entries (of about 5000 to 7000 words and neatly typed in double space on one side of the paper only) should be submitted in triplicate under a **Nom de Plume**. Full name and address of the competitor should be given on a separate sheet and enclosed in a sealed envelope bearing on the outside the **Nom de Plume**. All essays should be sent to Professor Kamal Nayan Kabra, Indian Institute of Public Administration, Indraprashtha Estate, New Delhi - 110002 by registered post so as to reach us by October 4, 1996. The envelope should be marked "ESSAY COMPETITION – WORLD FOOD SUMMIT 1996".

The value of one First Prize is Rs. 10,000/-, Two Second Prizes of Rs. 5,000/- each and Four Third Prizes of Rs. 2,500/- each. The essay will be adjudged by a body of judges selected by the IIPA. The award of the judges shall be final and no correspondence on this matter will be entertained. The Institute reserves the right not to make any award if none of the essays submitted reaches the necessary standard.

# Three generations of small savers. There's one thing they all trust-Units.

## Foreign Direct Investment and Domestic Savings-Investment Behaviour

#### **Developing Countries' Experience**

Biswajit Dhar Saikat Sinha Roy

Two main arguments have been advanced in support of the role of foreign direct investment (FDI) in stimulating growth processes in developing countries. The first, essentially a short-term view, maintains that FDI can help mitigate problems encountered in external debt management. The second takes a longer-term perspective while arguing that FDI has the potential of meeting the domestic resource gaps of developing countries thereby enhancing their growth prospects. This paper examines these two views by looking at the experience of 16 developing countries which have attracted the largest flows of FDI and have the largest stocks of FDI in the developing world.

IN recent years, the role of foreign direct investment (FDI) in stimulating growth processes, particularly in developing countries, has increasingly been emphasised. Two main arguments have been advanced in support of this view. The first, essentially a short-term view, maintains that FDI can help mitigate problems encountered in external debt management [Kume and Ito 1989]. The second takes a longer-term perspective while arguing that FDI has the potential of meeting the domestic resource gaps of developing countries thereby enhancing their growth prospects

The former view gained currency in the aftermath of the debt crisis that several developing countries encountered in the 1980s. It is based on the argument that FDI enables countries to manage their problems arising out of mounting external debt by providing an alternative source of long-term finance. The importance of this non-debt creating source of inflow was emphasised as several developing countries experienced negative net transfers on debt in the second half of the 1980s. Such negative transfers exposed the inherent vulnerability developing countries faced as they increased their dependence on private capital markets within a relatively short period of time. Among other measures that were employed in this situation was the debt-equity swaps, in which foreign investors offered to buy a predetermined volume of debt stock of the severely indebted countries at the going market rate and thus reduce the debt-overhang of these problem debtors. Although the debt-equity swaps did no become a major component of the debt management strategy adopted in the late 1980s, the importance of equity capital has increased quite substantially in the 1990s, while all other forms of capital flows to developing countries were increasing at vastly slower rates than in the past.

FDI flows, which in 1990 were \$ 25 billion increased to more than \$ 90 billion in 1995 (World Bank 1996). The importance of these flows in relative terms can be gauged from the fact that while in 1990 these flows were less than a quarter of the aggregate net resource flows to all developing countries, in 1995 their share had increased to nearly 40 per cent.

The long-term view of benefits arising out of FDI is based on the perception that such inflows of capital act as 'engines of growth' in developing countries [UN 1992]. It has been argued that FDI, by raising the levels of capital formation in host countries. significantly contributes to the countries' growth processes. FDI, according to this view, is seen as an important source of foreign savings for the host countries which augment their domestic resources available for investment. These above-mentioned views on the beneficial impact of FDI flows on host countries have, however, lacked adequate empirical basis. The absence of any systematic analysis to evaluate the role of FDI in enhancing the growth potential of developing countries in particular, stands out as one of the major deficiencies in the policy-related literature.

The present paper makes a modest attempt to examine the two views pertaining to FDI by taking into consideration 16 developing countries. Countries included here are those that have attracted the largest flows of FDI as also ones in which the stocks of FDI are the largest in the developing world.

The paper has four substantive sections. In the first, we would set the present study in perspective by briefly discussing some of the past studies that have dealt with the observed relationship between foreign capital inflows and savings-investment behaviour in the recipient countries. The second section discusses the pattern of FDI flows as well as outflows across countries included here by taking an 18-year span beginning with 1975 and ending with the most recent year for which data are available for most countries. This discussion allows an examination of what we have termed as the short-term view of the benefits arising out of FDI flows. The short-term view, as we had stated above, is that FDI can be useful source of counting the negative net flows that developing countries have experienced on account of other forms of capital flows. The third section would discuss the savingsinvestment behaviour in the sample countries for the same 18-year period for which we have analysed the behaviour of FDI. Alongside discussing the trends in savings and investment, this section also brings out the significance of FDI flows in the overall magnitude of investment undertaken in these countries. And finally, in the fourth section, we analyse the observed relationship between FDI flows and the savings-investment behaviour of the identified host countries. The implications for developing countries, growth would be drawn on the basis of this analysis.

#### Foreign Capital Inflows and Growth Prospects of Developing Countries

The impact of foreign capital inflows on economic growth of recipient countries has long been diseassed in received literature. Central to the analyses have been the influence of capital inflows on domestic savings and investment behaviour of the countries in question

In one of the early studies, Chenery and Strout (1966) provided a detailed exposition of the manner in which external resources could lead to increases in the overall rates of investment, and hence GNP, in developing countries. External resources, according to the authors, could enhance the growth potential of these countries by augmenting the domestically available investible surplus. The low levels of domestic savings. Chenery and Strout indicate, act as constraints on the investment activity, and consequently on the desired levels of economic growth. With external resources removing the limits on domestic investment, in other words stepping up investment rates, developing countries can launch into a path that would eventually result in self-sustaining growth."

The above framework provided by Chenery and Strout wherein foreign inflows are seen to result in a virtuous circle of growth for developing countries was however sharply divergent from the findings of an earlier study carried out by Haavelmo (1965). Haavelmo indicated that domestic investment in developing countries was directly related not only to the level of GNP but to capital inflows as well. From the above relation Haavelmo inferred that domestic savings in the recipient countries could be negative if

capital inflows were large enough. This was taken to imply that foreign inflows did not necessarily supplement domestic investment. The latter findings were confirmed by several subsequent papers testing the Haavelmo hypothesis [Rahman 1968; Ahmed 1971]. Rahman verifies Haavelmo's hypothesis showing that domestic savings is not a function of income alone but also has an inverse relationship with the inflow of foreign capital. The cross country data used in this study confirms the hypothesis and rejects the view that foreign capital is used only for increasing investment and not as a substitute for domestic savings. Corroboration of Haavelmo's findings were provided by later studies which included Griffin (1970) and Weisskopf (1972). In subsequent studies, however, this view has come to be analysed more closely wherein specific forms of capital inflows were considered.

Stoneman (1975) used a simple model to show in particular the impact of foreign capital in the form of FDI on the rate of growth of developing countries. Among the most significant findings of the study were that while aid and foreign inflows in general contributed to economic growth of the recipients, the stock of FDI was found to be negatively correlated with growth.

The relationship between FDI and savings and investment behaviour in host countries has been systematically observed in some studies. Notable among these is Areskoug (1976) which used data from 21 developing countries. The relationship between domestic capital formation and various sources of gross savings was worked out, FDI being included, FDI as one of the major components of savings. The study found a negative relationship between foreign capital inflows and capital formation in host countries.

Agosin (1994) has shown that in Latin American economies, foreign capital inflows since the late 1980s have not led to significant rise in investment rates in these economies. The study attributes this observed phenomenon to two factors: first, inflows have financed debt service payments, and secondly, the economic policies have led to dampening investment propensities with exchange rate appreciation and credit conditions remaining tight. UNCTAD has presented a more recent scenario of capital flows, savings and investment for the Latin American countries [UNCTAD 1995]. Contribution of the external sector to capital accumulation was found to be negative in the second half of the 1980s. The reason for this, the study points out, was that these countries were virtually cut-off from the international capital markets. But in the 1990s, despite capital inflows being significant, investment rates did not pick up as the corresponding domestic savings rates had fallen steeply. However, cross-country experiences in this regard were found to be varying. While in Chile, investment rates increased between 1990 and 1992 when the increase in capital inflows was only modest, in Peru and Argentina, investment rates fell despite sharp increases in capital inflows. The studies referred to above indicate the divergence of views that exist on the impact of foreign capital inflows on host countries. What is more important to note here is that there have been several studies which provided empirical basis while arguing that foreign capital inflows in general may have a less than favourable impact on the recipient countries. It is this view that would be examined in this paper by taking into consideration a specific set of countries and their experiences with FDI flows more closely in order that meaningful conclusions can be reached.

#### II Nature of Net Flows on FDI

The analysis in this paper is based on data covering 16 developing countries that have either been the largest recipient of FDI flows or have had the largest stock of FDI in the developing world in 1993. China, which has been by far the largest recipient of FDI among developing countries, has been excluded from the set of countries considered here since the nature of FDI it has attracted differs qualitatively from those of the rest. Unlike the other recipient countries, China has seen its non-residents contributing in sizeable proportions in the country's inward investment.

The data on FDI flows and outflows have been taken from the Balance of Payments Statistics of the IMF. Inflows on FDI are inclusive of re-invested earnings for all countries with the exception of Chile, Saudi Arabia and the Philippines. The outflows, for the purposes of this analysis, include the debit item of direct investment income on the current account. This comprises dividends and interest payments accruing to foreign investors, as well as earnings of branches of foreign companies. We have, in other words, included remittances arising directly out of FDI as outflows, all other payments that foreign investors are made have been excluded.

The analysis is based on data beginning with 1975 and ending with 1993, the terminal year being the most recent year for which data are available for most countries. At the outset, we would present the broad trends of net flows on FDI experienced by the sample countries. From the available data, the countries can be divided into two broad analytical groups based on the direction in which net flows on FDI have moved during the entire period taken as a whole under consideration. Nine of the 16 countries have experienced positive net flows and in the remaining seven, net flows have been negative (Tables 1 and 2).

Several interesting features of FDI behaviour can be seen from the tables. Singapore attracted the largest inward investment of nearly \$ 40 billion. However, this inflow was accompanied by considerably larger outflows which totalled more than \$ 49 billion. As a consequence, the negative net flows were close to a fifth of the total

Table 1: Inflows, Outflows and Net Flows for Countries Experiencing Positive Net Inflows on FDI (1975-1993)

(US \$ millions)

Source: Balance of Payments Statistics, IMF, various years.

flows of FDI coming into Singapore between 1975 and 1994. On the other hand, Mexico, which followed Singapore in terms of the magnitude of inflows, had a significantly lower level of outflows. While its inflows were over \$ 34 billion, the outflows were a modest \$ 11 billion in the entire period. The important aspect about Mexico was that positive net flows were recorded throughout. Aregentina was the only other country attracting sizeable volumes of FDI and which like Mexico had sizeable net inflows.

Malaysia and Brazil, the two other countries receiving large volumes of inward investment, had negative net flows on FDI during at best one quinquennium. But while Malaysia had negative net flows till the beginning of the 1990s, in Brazil, the net flows turned negative in the second half of the 1980s. Saudi Arabia is among the more interesting of the countries included in the set. The total FDI stock of the country in 1993 was among the highest in the developing world,6 but quite paradoxically it did not attract any fresh inflows of equity capital during the entire period considered here. The outflows were, however, of a sizeable magnitude as a consequence of which the country's net outflows were the largest amongst the sample countries, totalling more than \$ 57.5 billion.

The trends in FDI flows across countries show that with the exception of Brazil and the Philippines the increase in FDI flows had taken place after 1980. In Mexico, Venezuela and Thailand, increases in inflows were particularly significant during the 1980s, while Malaysia experienced on steep increase in FDI in the 1990s. However, FDI was not found to be rising by any significant measures in some of the more dynamic countries, as, for example, Singapore and Thailand in the more recent years. Malaysia was the only high growth country where there was a marked step up in inward investment. The country experienced a trebling of FDI flows in the first half of the 1990s as compared to the second half of the 1980s, an experience that was shared by Argentina.

The impact of the changes in the pattern of FDI on the growth possibilities of the host countries would be discussed below. The savings-investment behaviour in these countries would be juxtaposed against the pattern of FDI flows. But before this exercise is carried out in a later section, we would present the trends in savings and investment rates in the sample countries in the two decades for which we observed the FDI flows.

#### III Trends in Savings and Investment Rates

The savings-investment behaviour across countries would be discussed by considering four sub-periods covering the period 1975 to 1993; the choice of the latest terminal year was guided by the availability of data for most countries. The trends in savings-investment rates seen in the sample countries allow us to classify the countries into two

distinct groups. The first includes countries in the dynamic Asian region which show consistent improvement in both savings and investment rates. More importantly, these countries increased their rates of savings and investments from the moderately high levels they were recording during the second half of the 1970s. The only country in this region not to follow this pattern has been the Philippines, where the savings rate, in particular, declined quite sharply in the later phase. In contrast, most Latin American countries, with the exception of Chile, have experienced declining savings-investment rates. Of the remaining countries, while Nigeria and Saudi Arabia followed the Latin American pattern, Turkey was in the ranks of the dynamic Asian countries. These patterns notwithstanding, there are appreciable variations in savings-investment rates across countries in both the groups mentioned above. Among the east Asian countries. Singapore had consistently high rates of both savings and investment. Korea had investment rates reaching an average of 30 per cent during the second half of the 1970s, and after a relative stagnation in the 1980s, the rates recorded appreciable increases in the 1990s. The country's savings rate, on the other hand, increased quite sharply during the second half of the 1980s after which the rates declined somewhat. In case of Malaysia and Indonesia, savings rates were high throughout the period. But while Malaysia experienced sharply rising investment rates during the 1980s, in Indonesia, investment rates were bordering on stagnation. The most noteworthy case among the Asian countries is that of Thailand where both savings and investment rates increased phenomenally since the mid-1980s. The country's investment rate increased from an average of around 27 per cent during second half of the 1970s to nearly 41 per cent during 1991-93, and savings rate from around 22 per cent to over 35 per cent during the same period. Thailand's experience was almost replicated by Chile with its savings rate increasing from below 18 per cent in the late 1970s to over 29 per cent in the 1990s

The declining rates of savings and investment that most Latin American countries included here experienced led to a worsening of their already low rates prevailing in the 1970s. Exceptions to the low rates syndrome were Argentina and Venezuela where savings-investment rates in the late 1970s were comparable with those that the east Asian countries have registered in the more recent years. But by the 1990s, the countries saw a nearly halving of rates compared with the initial period. Furkey and Nigeria present cases of low savings and investment rates, though Turkey saw only marginal improvements in the rates during the entire period. Venezuela and Saudi Arabia are typical oil surplus economies with high rates of savings during the 1970s and a sharp decline thereafter

The significance of FDI in the overall investments undertaken by the countries in

the period under consideration is given in Table 3.7 Singapore is the singular case where FDI has made size able contributions to domestic investment, reaching a high of more than 35 per cent during the second half of the 1980s. In Malaysia, FDI was contributing to just over 10 per cent of investment on an average till the end of the 1980s, but in the 1990s, its contribution increased to about a fourth of the total investment. For Chile, Argentina and Mexico, there has been a definite improvement in the flow-investment ratio after the mid-1980s, and for Venezuela during the 1990s.

Source Same as in Table 1

The low shares of FDI in investments across countries in general indicate quite clearly that for the sample countries where total volumes of FDI inflows have been considerably high as compared to most developing countries, foreign investment has made only a nominal contribution to the investible resources. The real significance of FDI can really be seen by examining its influence on domestic savings-investment rates in the host countries, as is elaborated in the following section.

#### IV FDI and Savings-Investment Behaviour of Host Countries

The relationship between FDI flows and savings-investment behaviour of host countries is analysed for the sample countries with the help of a simple statistical exercise. The causality between FDI and investment behaviour is worked out by taking the figures for gross inflows of FDI and the gross fixed capital formation of the countries in question. The FDI-domestic savings relationship has been analysed by taking the net inflows instead.

The analysis here has been done using data from 1980 to 1993. The selection of the period is guided by our earlier observation that FDI flows in a majority of the countries included here started to increase appreciably only in the 1980s. The exercise would be carried out in two stages. In the first instance, correlations have been obtained between the two sets of variables for individual countries. A further exercise of obtaining the OLS estimates have been carried out for countries where the correlation coefficients are found to be significant.

In order to understand the relationship between FDI and domestic savings behaviour in the sample countries we have taken into consideration the net flows on FDI and savings rate (defined as domestic savings to GNP for purposes of comparability with the rate of FDI flows which also has GNP as the denominator). The results presented in Table 4 show that for most countries experiencing positive net flows on FDI, there are weak associations between FDI and domestic savings behaviour. Three countries do not follow this trend. Thailand and Turkey have a strong positive relationship, in case of Korea, the relationship is negative.

Several countries show that net flows on FDI and domestic savings rate have a negative causality. For instance, in Singapore negative net flows have been accompanied by upward movement in the savings rate. Similar has been the case of Peru and Columbia, the latter showing a particularly strong negative relationship. On the other hand, Mexico, Argentina and Nigeria have positive net flows in the entire period taken together, but the savings rates in these countries have in fact declined. Thus, the results obtained for the sample countries do not support the view that FDI is generally accompanied by improvements in the savings rates of host countries.

But while the above inference can be drawn quite appropriately for countries which have experienced only moderate levels of savings, a further explanation would be necessary, in our view, to establish its validity in respect of the high savers. The four east Asian countries, viz, Singapore, Korea, Malaysia and Thailand have had high levels of domestic savings during the entire period of our analysis here and it is therefore important to consider whether or not the savings-FDI link was established in an earlier phase. Table 3 shows that in all the abovementioned countries, barring Thailand, the historical break with the past trends of savings took place prior to the phase in which FDI flows had registered a similar break. All these countries, we had stated above, were recording high rates of savings even during the 1970s. It can therefore be said that domestic resource mobilisation played a key role in influencing the increased dynamism

these countries have witnessed particularly in the 1980s. We would examine this aspect further in the following discussion which deals with the likely influence of FDI on investment behaviour in host countries.

The observed relationship between FDI and investment varies significantly across countries (Table 5). The correlation coefficients are found to be positive and significance for six of the 16 countries in the sample. In case of Chile, the coefficient is positive but is insignificant and for Brazil. the coefficient is close to zero. Of these countries showing positive association between FDI inflows and domestic investment, Peru and the Philippines have experienced downturn in both variables, while for Chile the variables have been stagnating as between 1986 and 1993, 1 c, for a better part of the period considered here. Most of the remaining countries show low coefficients with a negative sign with

the exception of Argentina, which shows a strong negative relation between FDI flows and domestic investment.

The results would suggest that for most countries FDI inflows were not accompanied by any appreciable changes in their domestic rates of investment. What is striking is that this tendency can be seen prominently in countries such as Singapore, Mexico and Brazil, which have attracted very large volumes of FDI. Malaysia is the only country from among the larger host countries to FDI that shows improvement in the rates of investment with increased inflows over time.

Table 5 shows that FD1 flows and investment have a positive and significant correlation for Indonesia, Malaysia, Thailand, the Philippines, Peru and Turkey. However, for Peru and the Philippines, the observed correlations are over a declining trend in both variables. For Chile, the correlation coefficient is positive but is less significant while for Brazil, it was found to be insignificant. The other developing countries show a negative correlation between FDI flows and investment, but this is significant only for Argentina.

Certain important inferences can be drawn from the above results. The growth potential of the sample countries have not been enhanced by FDI in most cases as is indicated by the low or even negative correlation between FDI and domestic investment. This finding could be influenced by the low share of FDI in the domestic investment undertaken by most countries described in the previous section. The negative coefficients, particularly in case of countries like Singapore and Mexico, could be taken as an indication of crowding out of domestic investment at the margin. This conclusion can be made more strongly for Singapore where the share of FDI in domestic investment has been significant.

#### Conclusions

The potential benefits of FDI for the host countries were analysed by looking at the experience of the major destinations of this

torm of private capital. I wo dimensions of the potential benefits were considered. The first was regarding its contribution to the external debt management, particularly in arresting the increase in negative net transfers that had become a feature of the debt-creating privately sourced flows. The experience of several countries included here with FDI on this count has been far from encouraging. It was found that FDI had given rise to negative net flows, in some cases of large magnitudes, during the period for which data was presented.

Secondly, the influence of FDI on domestic savings and investment was analysed with the help of a simple statistical exercise. The results obtained show that for most countries in the sample, FDI flows were not accompanied by any significant changes in the savings and investment rates in the host countries. This, in other words, implies that FDI would have a limited role in raising the growth potential of the recipient countries. The lack of significant relationship between FDI and domestic investment could be influenced by the relatively small share of the former in the investments undertaken by the sample countries. But this fact also underlines the point that the true potential of FDI in developing countries has been mostly overstated. More importantly, our findings suggest that in countries like Singapore and Mexico, both of which attracted large volumes of FDI, there may have been a crowding out of domestic investment. Thus, instead of complementing domestic investment efforts, FDI may well be acting as a substitute to the local efforts at promoting investment activity.

#### Notes

[Comments received from Sunanda Sen are gratefull acknowledged.]

- Balasubramanyam, Salisu and Sapsord (1996) found that FDI induces growth in developing economies, more strongly for export promoting economies than for import substituting ones
- 2 The model that provides the basis for this conclusion arrived at by Chenery and Strout has a three-phase structure. In Phase I, external resources help in augmenting domestic investible surplus in order to help realise the target rate of growth. The requirements of capital inflows could decline in Phase II as incremental savings rate exceed the investment rate, but the system could encounter another limit on the growth prospects arising out of trade imbalances and this could again step up the capital inflows For, the inflows to be reduced and the economy become self-sustaining, the model laid out requires that in Phase III, export growth must exceed that of imports
- 3 The functional relationship seems to be holding is: I(t) = a [Y(t) + H(t)], where, I=gross investment, Y=GNP, and H=capital inflows.
- 4 The World Investment Report 1995 identifies the top 10 countries in terms of FDI flows and stock [see UN 1996:Table 1.3, p 12]. In addition to these countries, we have included the other major destinations of FDI in the developing world.
- 5 Payments due to technology imports are among

- the major indirect effects of FDI that recipient countries have to be contend with
- 6 World Investment Report, 1995 (Table 13, p 12) indicates that the stock of FDI in Saudi Arabia was US \$ 22,463 million in 1993.
- 7 To compute the flow-investment ratio, one confronts with the problem of comparability of the data. The data for FDI is obtained from Balunce of Payments Statistics, IMF while the source of data on domestic investment is World Bank's World Tables We have used the ratio of FDI to domestic investment as a broad indicator of the relative significance of FDI across countries.

### A Short-Cut To Global Technology

You need World-Class Technology But you don't want to scout the globe trying to locate it

Talk to Bharat Electronics We're India's premier professional electronics Company, with a reputation for quality and leading edge technology that goes back four decades. Supported by a workforce that's 18,000 strong including 2000 Engineers

Bharat Electronics is geared to meet your demands In Defence Radars, Defence Communications, Telecommunications, Satellite Communications, Sound and Vision Broadcasting, and in variety of sophisticated Semiconductor Electronics. Even to help you source PCB assemblies manufactured in our state-of-the-art SMT assembly line. Or finding Total System Solutions as per your individual requirements. Bharat Electronics Ltd, certified by the ISO 9000 series is a short cut to your hi-tech electronic needs.

#### PRODUCT RANGE

- Defence Communication Equipment in HF, UHF, VHF Microwave Bands, F2/F3 Intelsat Stations.
- Telecommunication Networks, Radio Multiplexing and Switching Equipment • Antennae • Broadcast and TV Transmitters and Studio Equipment
- Satcom Terminals for Communication and TV Networking • Radars for Defence and Meteorology
- Optical and Opto-electronic Equipment
   Simulators and Software
   Semiconductors, ICs, Crystals, LCDs and Electron Tubes, Microwave Tubes, Transmitting Tubes, X-ray, TV & Monitor Tubes.

#### **India's Capital Market Growth**

#### Trends, Explanations and Evidence

#### R Nagaraj

This study, first, documents India's capital market boom, and its proximate causes. What does it mean for the economy and private corporate sector? It is largely disintermediation: household sector substituted 'shares and debentures' for bank deposits, and corporate sector securitised its debt. There is no association netween growth rates of the capital market mobilisation and aggregate saving rate, corporate physical investment and value added. Long-term decline in the contribution of internal finance to corporate fixed investment and in profitability in 1980s are noted, despite a fall in ratio of corporate tax to gross profit. The study concludes by raising some questions.

FOR some time now, the capital market in India is much in news. There is a widespread appreciation of the private corporate sector's (corporate sector, hereafter) ability to issue a growing volume and variety of marketable securities, as this suggests an increasing role for markets in the economy's resource allocation. It also raises many questions. What does the trend imply for the economy's aggregate saving rate and its composition, and for corporate performance. Is it necessary and desirable for the economy's long-term development prospects? This study seeks to explore these and related questions.

Section I describes long-term trends in India's capital market growth. To understand them, Section II briefly reviews the recent literature. On this basis, Section III examines the implications of the observed trends for the economy and the corporate sector. Summarising the main findings, the concluding section raises some questions that seem to follow from the capital market development.

#### I Trends

After remaining dormant for nearly two decades since around 1960, resource mobilisation in the primary capital market showed an upturn from the late 1970s (Figure 1). The growth accelerated towards the end of 1980s. The market capitalisation ratio went up from about 5 per cent of GDP in 1980-81 to 63 per cent in 1992-93.2 In eight years after 1986, the average daily turnover in the secondary market grew at about 35 per cent per year. Between 1980-81 and 1992-93, the RBI index of securities prices increased almost thrice (20.7) per cent per year) as fast as the wholesale price index (7.6 per cent per year). This, in principle, reduces cost of equity capital and increases prospects for capital gains.

However, much of the growth is for debt securities. About a third is for convertible debentures. Proportion of equity (or risk) capital in market mobilisation came down from about 90 per cent in the early 1970s to about 30 per cent two decades later (Figure 2). However, in absolute terms, nominal value of fresh equity capital raised grew at 18 per cent per year. Promoters' contribution in this more than doubled, from 21 per cent in 1970-71 to 45 per cent in 1990-91. This, in principle, is a favourable change as they now have a greater stake in the companies' financial success (Table 1).5 Proportion of equity underwritten also rose steadily, reflecting the stock market's growing maturity [Samuel 1996a]. Moreover, the market witnessed growth of new financial institutions offering a variety of services and tradable instruments with varying components of debt, equity, maturities and risk.6

How does India compare with other 'emerging market economies '(EME)? Reportedly, India is the biggest among them with about 8,000 quoted companies in 1995, an increase of over 70 per cent over the last decade (*The Economist*, July 6, 1996).7 In market capitalisation, India ranked seventh in 1995 (*The Economist*, July 15, 1995).\* However, as Indian firms are small (measured by market capitalisation), they do not figure in the list of top 30 firms in EMEs (*The Economist*, August 12, 1995).

What explains the capital market growth? Proximate causes are a series of policy initiatives since around the late 1970s when, as mentioned, the stock market had a marginal role in financing industry. Initially, dilution of equity holding in foreign-controlled rupee companies - popularly called the 'FERA companies', as they attracted this 1973 act -- was perhaps a conscious effort to stimulate the primary capital market [Morris 1985]. FERA companies' success was probably significant for further development of the market.

This broadly coincided with the rise in nominal interest rates and the financial sector's growing resource constraint. With increasing reserve requirement and 'priority sector' lending targets at concessional interest rates, commercial banks reportedly could not meet the industrial sector's credit needs. In these circumstances, development finance

institutions (DFI) persuaded firms to raise part of the required funds from the capital market. <sup>12</sup> Anticipating corporate sector's resource constraint in the Sixth Plan (1981-85), government initiated many steps to encourage flow of household saving into capital market [Planning Commission 1982]. <sup>13</sup> These included hike in interest rates on debt instruments, their convertibility into equity, raising of tax exemption limits on dividend income and easing its (and interest) deduction at source. Similarly, corporate tax rates were reduced. <sup>14</sup> Thus capital market reforms since 1991 perhaps reflect a continuation of a trend initiated over a decade ago. <sup>15</sup>

What do these trends (and policies that seem to underpin them) imply for long-term development? Do they represent a 'natural' evolution of a 'repressed' financial system towards a more 'market-oriented' system with a greater need for regulation, as the Narasimham Committee noted [Government of India 1991]. Does it necessarily mean a greater allocative efficiency as resource use is increasingly market determined? Are there alternative 'models' or 'systems' of financial development to choose as our trajectory. To explore these questions, the recent analytical literature and comparative experience is briefly reviewed below.

#### II An Analytical Sketch

For much of the recent literature on financial markets, Mackinnon (1973) and Shaw (1973) form the points of departure These studies argue that state intervention in setting interest rates and quantitative measures of resources allocation - defined as financial repression -- adversely affect not only allocative efficiency but also depress the aggregate saving rate (hence investment) in less developed economies (LDCs). Therefore, they advocate liberalisation of financial markets. However, their arguments are mostly related to interventions in banking, like interest rates ceiling, statutory reserve requirements and directed lending programmes at concessional interest rates.

FIGURE 1: CAPITAL RAISED IN INDIA'S PRIMARY CAPITAL MARKET IN NOMINAL TERMS, 1960-61 to 1992-93

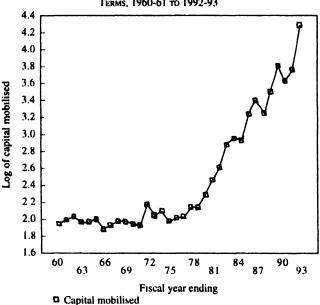

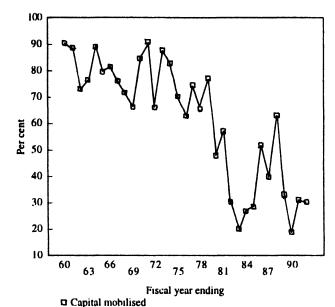

Figure 2: Share of Equity in Fotal Capital Mobilised, 1960 to 1992

Source. RBI Report of Currency and Finance, various issues

Source: RBI Report of Currency and Finance, various issues

Extending their thesis, Cho (1986) argued that financial market liberalisation may remain incomplete without an efficient market for equity capital as a means of spreading risk (and reward).<sup>16</sup>

In principle, stock market, as a part of a well organised financial system, has many advantages. It allows efficient risk sharing. Stock market induces gathering of information which gets reflected in stock prices. These prices are then signals for resource allocation. In the secondary market, stock prices are powerful signals for managerial incentives and corporate governance.

Attributing part of the debt crisis of the 1980s in LDCs to inadequate development of their financial markets, the World Development Report (WDR), 1989 [World Bank 1989) broadly reflects the preceding analytical position. However, recognising information failure that can be acute in financial markets, the report argues for a sound supervisory mechanism and institutions to ensure their efficient functioning. On these considerations, the World Bank (and its affiliate, International Finance Corporation) makes policy-based lending and offers technical assistance for capital market development. Stock market growth in many LDCs in recent years perhaps reflects these policies and financial incentives. In India too, of late, much of the policy discussion seems to follow this dominant thought.

Till some time ago, shortage of long-term capital was believed to be a major constraint on industrialisation, since banks supply only short-term loans. As capital markets were practically non-existent (or reportedly

inefficient) in most LDCs, state promoted DFIs (often supported by World Bank's advice and lines of credit) were expected to make up for the absence of an efficient capital market. Keynes' precepts about inefficiency (and fickleness) of the stock market and banks' limitation in meeting long-term financial needs of industrialisation perhaps underpinned much of the earlier policy.<sup>17</sup> Gerschenkron's (1962) historical account offered empirical support for it.<sup>18</sup>

Many believe one of the reasons for the post-war success of Japanese and German growth and productivity is the difference in their institutional set up for financing industry [Zysman 1983, Dore 1985, Dimsdale and Prevezer 1994]. In these economies, large firms and banks have close financial (and managerial) links, while stock markets are relatively small and illiquid. Hence, firms reportedly take a long-term view of corporate success. In contrast, firms in the US and UK have arms length relations with banks. Firms are apparently more concerned about shortterm prospects as their market valuation depends on quarterly/half-yearly financial performance.19 A growing opinion seems to find the US system of stock market - though efficient and liquid - unsatisfactory for corporate governance. [Bhide 1994].

Another reason for questioning capital markets' role in financing development is the recent empirical research that revived the 'financing hierarchy' hypothesis in corporate finance literature [Koch 1943, Donaldson 1961]. Contrary to the widely held belief, Mayer found, using company balance sheet data, that internal resources finance bulk of corporate (physical) investment in major OECD countries and stock market's role

(net of redemption) is very limited. To quote him:

The first is that retentions are the dominant source of finance in all countries...where external finance is raised it generally comes from banks rather than from securities

market...stock markets contribute very little to new sources of finance for companies: new equity issues account for well under 10 per cent of the total sources of finance raised by companies in all major OECD countries... bond markets are a relatively minor source of finance for industry in aggregate in all countries other than the US and Canada. [Mayer 1992: 465]<sup>20</sup>

Reiterating the same stylised fact, Stiglitz highlights problems of information failure that are severe in financial markets and notes the need for state intervention [Stiglitz 1991, 1993]. He says, "... we must bear in mind the quite limited role that they [market for equity | play in raising capital in developed countries. Hopes of raising substantial amounts of capital in this form within LDCs appear to me to be unreasonable." In a footnote, he further adds, "Today, investors in LDCs bring to bear the full experience of how equities have been abused, even in societies with fairly well functioning legal systems. This should make them wary about what would happen in LDCs" [Stiglitz 1991:11].

Thus, we seem to have two broadly competing perspectives. One, the financial liberalisation thesis that emphasises centrality of stock market in resource allocation and the secondary market's disciplining role (with independent supervision) on managerial behaviour. Two, information economics theorists who, on theory and history, argue for its limited role.

In development economics, stock market did not receive adequate attention as it is a recent phenomenon in LDCs. To our knowledge, Singh and Hamid (1992) and Singh (1995), analysing corporate financing pattern of top 50 (100) private corporate firms in nine (ten) EMEs in 1980s, are significant efforts.<sup>24</sup> Contrary to the OECD experience they find, on average, equity capital finances about 40 percent of corporate investment growth in these economies.<sup>22</sup> However, noting the limitations of sample size and methodology, Cobham and Subramaniam (1995) seriously quality Singh's finding. Following Mayer's methodology, they show a much limited role for equity in financing corporate growth in India. To quote them:

...India is broadly comparable to. France and Italy which have relatively small stock market (with no market for corporate control), large sectors of medium and small

sized companies and a banking system which lends substantial amounts to companies but does not have very close ties with firms and cannot exert the same influence and control over them typical of Japanese banks [Cobham and Subramanian 1995; 31]

Mindful of the OECD experience and analytical limitations of the financial liberalisation thesis, Singh (1992) suggested that the real test for capital market in developing economies is its effect on saving, investment and growth. To quote him.

the important question is whether the development of the stock markets in these economies has led to an increase in aggregate savings or whether it simply represents the substitution of one form of saving (say bank

savings or government bonds) for another (purchase of corporate shares in stockmarket)...it could be argued that the stock market is still useful insofar as it leads to a more efficient allocation of these savings or to better corporate performance as a result of stock market exposure (pp 38-39, emphasis as in the original).

The preceding brief review helps us ask elevant questions about the recent Indian experience. What does capital market growth nean for domestic saving rate, corporate nvestment rate and output growth? What proportion of physical investment is financed by internal resources? Has it changed since he capital market boom? Does capital market nobilisation represent additional resources or investment or a substitution of external inance for internal resources? Has the composition of external finance changed in ecent years? Is capital market boom issociated with improved corporate perormance? The following section examines hese questions empirically.

#### Ш **Evidence**

#### India's Corporate Sector: A Brief Account

In this study, the corporate sector is lefined as non-financial, non-government oint stock companies. As this sector accessed bulk of the capital market resources, it will be useful to begin by Jescribing the broad dimensions of this sector. In 1994, it consisted of about 3.4 akh registered companies [Department of Company Affairs 1995]. Slightly less than half of them are engaged in manufacturing and about a quarter in 'finance, insurance, real estate and business services'. However, bulk of corporate value added originates in registered manufacturing. Only about 12 per cent of the corporate sector are public limited companies, yet they account for about 86 per cent of the total paid up capital. Among public limited companies, the top 670 companies accounted for 43 per cent of net value added in the corporate sector in 1986-87.11 Only about 2 per cent of public limited companies accessed capital market in 1993-94.

Corporate sector constituted 11 per cent of current GDPfc in 1986-87 (about 9 per cent in 1960-61), and about 27 per cent of non-agriculture, private sector GDPfc.24 Within the corporate sector, public limited companies' share in value added declined by 10 per cent (from 80 per cent), over two and a halt decades from 1960-61. This seem to broadly correspond to faster growth in the number of private limited companies. In other words, private limited companies, representing mostly small and closely held firms, increased their share in corporate sector value added 25 These statistics show the relative size of India's corporate sector and the (skewed) distribution of firms in it

#### Trends in Aggregate Saving and Its Composition

As is widely known, India's gross domestic saving rate (GDS) after peaking at 23 per cent of GDP at market prices (GDPmp) in 1978-79, fluctuated around 21 per cent for about a decade, till it regained the earlier level in 1990-91. Figure 3 shows five-yearly average in GDS since 1950-51.26 The share of financial saving in GDS rose steadily from 20 per cent in 1970-71 to about 55 per cent in 1984-85. However, it declined to about 40 per cent in the second half of 1980s, though it has improved somewhat subsequently (Figure 4). Therefore, no association exists between capital market growth and aggregate saving rate (or its share in financial assets).27

However, in the 1980s financial saving's composition shifted away from bank deposits to 'shares and debentures', with little change in the share of resources accruing to government through contractual saving schemes, like provident fund (Table 2). Between 1980-81 and 1992-93, the proportion of 'shares and debentures' in financial saving increased four times, from 5 per cent to 21 per cent. Therefore, the growth of (primary) capital market mobilisation represents a substitution of tradable securities for (fixed interest rate) bank deposits. Higher than bank interest rate on debentures, with opportunities for capital gains (in case of convertible debentures) and tax saving (in case of tax-free public sector bonds) are perhaps responsible for the shift in the portfolio.28

#### CHANGING PATTLEN OF CORPORATE FINANCE

This subsection uses three sets of time series data: (i) Datta Roy Chaudhury (1992) for 1955-56 to 1986-87, (ii) RBI finances of medium and large non-financial public limited companies, 1960-61 to 1991-92 and (iii) flow of funds (FOF) of private corporate business sector, for 1951-52 to 1991-92. We use balance sheet data as welf as FOF table covering overlapping time periods to ensure robustness of our findings. Our effort seems an improvement over Singh (1995)

as well as Cobham and Subramaniam (1995) since we use data for the entire private corporate sector, and for three to four decades.

A significant long-term trend is a decline in share of internal finance in corporate physical investment. According to the Datta Roy Chaudhury series, gross internal finance as a proportion of (nominal) gross fixed capital formation at (GFCF) declined from a high of 126.5 per cent to 39 per cent between 1966-70 and 1985-87 (Table 3, column 1). In the RBI series (column 3), ratio of gross internal finance and (nominal) gross capital formation (GCF) also show a similar trend, though the extent of decline is less. The trend is broadly similar on a 'net' basis as well.30 In the Datta Roy Chaudhury series, ratio of net retention (retained earning) and (nominal) net fixed capital formation peaked during 1971-75 and reached a low of 5 per cent during 1986-87 (column 2). Using National Accounts Statistics (NAS) also, the ratio shows a similar trend, though it improved by early 1990s (column 4). FOF data for four decades since 1951-52 confirms these changes.31 This seems significant, as it is at variance with the trends in the developed economies. As mentioned earlier. Mayer showed that in all major OECD countries internal finance forms a high and stable proportion of capital formation.

In India, the share of internal finance fell, despite a secular decline in corporate tax provision as a proportion of gross profit, from about 40 per cent in mid-1970s to about 15 per cent by the end of 1980s (Figure 5). This perhaps questions the widely held view that tax reduction increases corporate sector's internal resource generation.

What happened to the composition of external finance with capital market growth? The RBI series show that the share of fresh paid-up capital (including premiums) in total external finance increased from 4.4 per cent during the second half of 1970s to 11.3 per cent a decade later (Table 4). This level of equity financing is comparable to that during 1960s. <sup>12</sup> A similar change in external finance's composition is evident as a proportion of corporate gross capital formation also.

However, the share of borrowing ha remained stable at over one-half of externs finance in 1980s. Therefore, increase i equity finance has compensated for th decline in the share of trade credit. However composition of 'borrowing' has changed shares of banks and fixed deposits hav come down significantly, with a corresponding increase in the proportion of debenture (Table 5).

FOF data since 1951-52 are also consister with these observations, suggesting that muci of the growth of capital market represent substitution of securitised debt for ban credit, trade credit and fixed deposits (wit a limited increase in equity financing (Table 6).

In principle, greater reliance on externa finance subjects firms to the constant scrutin of capital market. If increase in share c external finance boosts corporate investmer rate, it may be desirable since, as Singh an Hamid noted, many rapidly industrialisin economies like South Korea display such pattern. As Table 7 shows, in India, corporat GFCF as a proportions of (i) GDPmp an (ii) aggregate GFCF increased in the secon half of 1980s.

However, is this association statisticall significant? Over three decades since 1961-62 (nominal) annual growth rates of capita raised and corporate GFCF have a statisticall significant positive correlation (Table 8 However, the correlation turns statisticall insignificant for the period since 1980-81

when the capital market boomed. The same finding holds with one year lag also. Therefore, on the face of it, the hypothesis that capital market resource mobilisation could have favourably influenced corporate physical investment growth does not seem valid.

Arguably, capital market boom may have contributed to output growth by encouraging better use of existing capital stock. This does not seem to be true either. Growth rate of real net value added in corporate manufacturing is lower than that of registered manufacturing as a whole (Table 9).<sup>33</sup> This holds for 1973-74 to 1990-91 as well as for its sub-period, 1980-81 to 1990-91, when manufacturing output growth witnessed an upturn. This means (as noted earlier), small sized, non-corporate firms have contributed more to the improvement in manufacturing growth rate in 1980s than the corporate sector.

Is the capital market boom then associated with improved corporate profitability? Datta Roy Chaudhury data suggest that profitability (gross profit as percentage of capital employed) fell sharply by 7 per cent. from around 19 per cent during 1981-87 (Figure 6). This is consistent with Singh and Hamid's estimates for top 50 companies for 1980-88. During the three decades since 1960-61, corporate sector's profit margin (profit before tax as percentage of total income) has come down by more than half (Table 10). Profit before tax as percentage of net assets and profit after tax as percentage of net worth (representing return to investor) show a gradual decline since the mid-1970s. However, these trends may have changed somewhat in the 1990s, though the evidence is limited for two years.

One could argue that real efficiency gain in securities market is likely to come from contestability of managements through threat of take-over. This question is as yet largely hypothetical. since this route to possible efficiency gains is legally restricted in India.

To answer the questions that we posed (quoting Singh) in the last section: there is little association between capital market resource mobilisation and aggregate saving rate, and corporate physical investment and output growth rates. As Singh speculated, primary stock market growth seems to represent households sector's substitution of 'shares and debentures' for bank deposits. Firms securitised their debt, instead of getting it from banks, or as trade credit and fixed deposits. These developments represent financial disintermediation that many OECD countries witnessed about a decade ago. 14 No statistically valid relationship exists between growth rates of capital market mobilisation and corporate physical investment (and output) in manufacturing. Significantly, corporate profitability declined in 1980s when capital market boomed." In other words, with capital market growth, an increasing share of loanable funds have accrued to a sector that contributed relatively less to output growth and that did not improve its investment rate either.

#### IV Conclusion

In sum, India's capital market witnessed a rapid growth since around 1980. It accelerated by the end of the decade. This is also significant in comparison with other emerging market economies. Increases in nominal interest rates since early last decade, incentives offered on traded securities, and changes in related policies (and procedures) seem responsible for this development.

The financial liberalisation thesis posits its likely positive effect on the economy's saving, investment and efficiency. A well functioning stock market also has a screening and monitoring role. However, recent advances in analytical literature highlights the possible inefficiencies in financial markets due to imperfect information that could be acute in LDCs, and underscores the need for state intervention. Further, reviving the financing hierarchy hypothesis, the new evidence on corporate financial structure in major OECD countries shows that the stock markets contributed very little to fixed investment. Secondary market's role in improving corporate governance is also open to a serious debate both on theoretical and empirical grounds. In the light of these competing perspectives, this study examined the implications of the India's capital market boom for the economy and the corporate sector.

Capital market growth has changed domestic financial saving's composition from bank deposits to 'shares and debentures', without favourably influencing domestic saving rate, or its share in financial assets. Equity capital's share in the total capital market mobilisation declined, as bulk of such mobilisation is in the form of debt securities. However, growth rate of fresh equity capital raised is substantial. Promoters' contribution to it has more than doubled. This could possibly improve financial

performance as promoters have a greater stake in their firms.

Over the last two decades, the corporate sector that secured most of these resources witnessed a long-term decline in the share of internal finance in corporate physical investment. In mid-1980s, retained earning accounted for less than 10 per cent of gross internal resources. This happened, despite a steady fall in tax burden (tax provision as proportion of gross profits). These changes are quite at variance with the developed countries' experience, where internal finance forms the largest and stable source of finance for corporate capital formation.

In 1980s, composition of external finance shifted away from trade credit to equity capital (including share premium), while the proportion of borrowing remained high and increased somewhat. However, within borrowing, debentures replaced bank credit and fixed deposits.

There is no statistically valid association

## BRINGING MADHYA PRADESH ON THE WORLD STAGE

Pradesh, the 'STI Group' with its flagship company 'Steel Tubes of India', has done the country proud. It has attained a national identity as the largest manufacturer of Precision Steel Tubes with applications in automobile and bicycle manufacture and the energy sector. It is rapidly acquiring a potentially growing presence in other thrust sectors such as Granite, Power, Textiles, Autocomponents, Financing & Investment and International trading

STI has forged successful joint venture in Singapore in Precision Steel Tubes with giants like Kobe Steel Ltd. and Tokyo Boeki Ltd., collaborative links with Breton Spa. of Italy in Granite & with Carl Froh Rohrenwerk of Germany in Copper Coated Tubes EEC (Brussels) has accorded a unique mark of approval to STI Group by selecting 'STI Granite' a 100% EOU for its first ever equity investment in India in the Private Sector.

STI Power India Ltd., a new Public Ltd. Company set up recently for executing the Prestigious Rs 1200 crores, 330 MW power project at Guna in M. P has well known international partners. The Group is also going ahead with a major 200 crore textile spinning unit in M. P.

With its emergent national stature and powerful global connections, the STI Group is all set to reach for the stars.

between capital market resource mobilisation and growth in corporate fixed investment or growth in this sector's real value added. Thus, we have witnessed, mainly, financial disintermediation, with little effect on aggregate saving rate and corporate investment and output growth rates. This seems similar to what happened in many developed economics with financial deregulation about a decade ago. All indicators of corporate profitability show a decline in 1980s.

If our findings are valid, they appear significant. The widely held view of positive effects of stock market growth on the economy's real sector, perhaps, needs to taken with caution. Moreover, the findings seem to raise many questions. How could corporate sector access such large resources when its profitability was steadily declining? Why did the share of retained earning decline when the corporate tax burden fell? Is the fall in profitability related to decline in share of internal finance? Finally, and perhaps more fundamentally, if capital market has little relation to corporate investment rate and output growth rate, what does capital market growth mean for the economy9 Is it, then, merely a side show?36

Capital market is not just an institution for resource mobilisation, but equally important, a market for corporate control that necessarily follows. Assume that, over time, widely perceived capital market imperfections are overcome with better regulation and technology. Are we, then, prepared for contestability of corporate management through mergers and take-overs in the secondary market? Assuming such a market is organised efficiently, does it necessarily improve corporate performance? These widely debated issues in developed economies seem to have an increasing relevance for India.

The Anglo-Saxon 'model' of corporate governance reportedly leads to 'shortism' as investors have arms length relation with managers. Threat of take-over apparently leads managers to resort to short-sighted policies, at the expense of long-term goal of growth and technical progress. In contrast, German and Japanese firms, that have close links with their banks, are said to be free from such pressures to show immediate results, and hence are able to take a long-term view of the firm's prospects.

In other words, the critical question is, what sort of a market economy we intend to move towards: is it the Anglo-Saxon 'model' with the primacy of capital market emphasising 'efficiency' and liquidity with the attendant shortism of corporate managements, or the German and Japanese styles of bank centric corporate governance with limited role for stock market but primacy to long-term growth and technical progress.<sup>37</sup>

These issues perhaps cannot be ignored any longer.

#### **Notes**

[Following the usual disclaimers, I thank Subir Gokarn, Veena Mishra, K V Ramaswamy, J C Sandesara, S L Shetty, M H Suryanarayana and Rajendra Vaidya for their comments on an earlier draft of this paper. I am particularly grateful to Cherian Samuel for his detailed comments and suggestions.]

- 1 In this paper 'capital market' is used narrowly to refer to India's stock markets. Strictly, stock market refers to issuing and trading of equities. Since the bulk of resources mobilised in Indian stock markets are debt securities, we prefer, for convenience, using the term capital market.
- 2 Market capitalisation ratio, is the market value of all traded shares, as a proportion of current gross domestic product at factor cost (GDPIc) This is a widely used measure of stock market size.
- 3 Though the secondary stock market has grown substantially both in absolute and comparative terms, one has to recognise its narrow base. In 1992-93, top 50 firms account for over two thirds of trading volume in Bombay stock exchange that does over 70 per cent of trading in all stock exchanges in India [CMIE 1994, Machiraju 1995].
- 4 A convertible debenture is a debt instrument, which is (or can be) partially or fully converted into equity share(s) at predetermined time and ratio, as specified in the initial public offer.
- 5 Increased promoters' contribution could partly be an illusion, as those eligible for contributing to promoters' share may have been enlarged. One suspects that in a regime of licensing and capital controls with booming securities prices, promoters' quota could have been used to dispense favours, similar to Japan's 'Recruit scandal' some years ago.
- 6 In 1980s a number of financial services firms like merchant bankers, underwriters, mutual funds, custodial services, etc, came into existence, mostly by existing public sector banks and financial institutions. Some of them were discredited in the 1992 stock market scam. However, since 1991 private sector firms including many with foreign origin also entered these newer industries. Instruments are convertible debentures, variety of mutual funds, etc. See Machiraju (1995) for descriptive details.
- 7 This is an overestimate due to double counting We know, a significant proportion of firms is listed in more than one stock exchange in India Bombay stock exchange, oldest and busiest of all, listed 2,601 companies in 1992 [CMIE 1994] This figure, we guess, is more accurate
- 8 Demirgue-Kunt and Levine's (1995) stylised facts seem to underestimate size of India's stock market. In their set of 41 countries, India ranks 31st in market capitalisation, with 16 per cent of GDP, during 1986-93.
- 9 Documenting India's financial development up to 1977, Goldsmith (1983) said "The open capital market has been only a secondary source of funds for corporate business. Thus, the market for corporate issues seems not to have developed since independence, and, in

addition, to have lost considerably in importance" (pp 204-06)

In describing India's financial system and structure. Raj (1992) perhaps did not find capital market significant enough to mention it

- 10 Foreign Exchange Regulation Act (FERA), 1973, required all foreign-controlled ruped companies to dilute foreign equity hold to 40 per cent, though the law's implementation depended on the firms' relative bargaining power vis-a-vis the government. However, in most cases, these firms did not disinvest their holding. Instead they issued fresh equities to Indian public, thus reducing their share in the paid-up capital, without losing their controlling interest in most cases.
- Rao's (1980) conclusion aptly reflects the dominant opinion before the capital market boom, " .industrial units have relied heavily for finance on the public financial institutions and banks, and have raised relatively little capital from the market with reordering of priorities over the last decade, an increasing proportion of resources of the commercial banks are channelled to other uses such as meeting increased reserve requirements and credit to priority sectors. Industrial expansion, therefore, must rely on raising more capital from the market industrial units can be encouraged to meet their financing requirement from a wide range of investors through marketable securities that can assist in the development of capital market" (pp 153-54)
- 12 Observing that firms depend on banks and DFIs for finance, and households invest in bank deposits. Patil (1979) argued for greater participation of household sector in financing firms' equity capital. Flus led to an interesting debate, mostly by practitioners of finance, on the need to develop capital market as a source of risk capital. See also, Chitale (1980)
- 13 Lall (1983) offers a critical comment on the assumptions underlying the Committee's recommendation that seem relevant even now.
- 14 CMIE (1986) documents these changes in policies and procedures
- 15 World Development Report, 1989 highlighted success of India's capital market reforms [World Bank 1989 108]
- 16 To quote Cho, "In a credit market with imperfect information, liberalisation of the banking system would not, by itself, be sufficient to achieve full efficiency. This is due to the adverse selection effect (and also the moral hazard effect) that occurs when debt contracts are used in the presence of asymmetric information. Equity contracts however, are free from adverse selection effects and could thus overcome inefficient allocation of capital when the same degree of imperfect information on borrowers exists as in the case of debt contracts" [Cho. 1986-198]
- 17 To quote Keynes' well known remark on Wali Street, "In one of the greatest investment market in the world, namely New York, the influence of speculation is enormous. Speculators may do no harm as bubbles on a steady stream of enterprise But the position is serious whenenterprise becomes the bubble on a whirlpool of speculation. When the capital development of a country.

- becomes a by-product of the activities of a casino, the job is likely to be ill done. The measures of success attained by Wall Street, regarded as an institution of which the proper purpose is to direct new investment into most profitable channels in terms of future yields, cannot be claimed as one of the outstanding triumphs of laissez-faire capitalism..." [Keynes 1936].
- 18 To quote Gerschenkron, "Depending on a given country's degree of economic backwardness on the eve of industrialisation, the course and character of the latter tended to vary in a number of important respects. Those variations can be readily compressed into the short hand of six propositions. The more backward a country's economy, the greater was the part played by institutional factors designed to increased supply of capital to the nascent industries." [Gerschenkron 1962].
- 19 Dore (1985) says, "The senior British manager, it is said, is bothered about the bottom line in his next half-yearly results, the Japanese manager about his market share in five years time. The Japanese manager is more concerned with long range planning, more assiduous in gathering information about the probable state of markets and the directions to be taken by technological development over the long-term" (p. 10).
- 20 Quite at variance with the WDR view, Mayer's background study for the report cautions against a benign view of stock market development. Tilting it provocatively, Myths of the West Mayer (1989) makes following 10 observations, based on his studies using corporate balance sheet data.

Retentions are the dominant source of finance in all countries (p 9)

There are some marked variations in self financing ratios across countries. In UK and US more than three quarters of investment is funded from retentions. In France, Japan and Italy, appreciably more is raised externally. Canada and Germany lie somewhere between the two groups (pp. 9-10).

In no country do companies raise substantial amount of finance from securities market (p. 10)

Banks are the dominant source of external finance in all countries

Bank finance is particularly pronounced in France Italy and Japan. It represents a surprisingly small proportion of German corporate financing.

UK investment has been consistently financed from retentions (91 per cent on average). Bank finance has contributed close to zero (3 per cent on average) on a net basis.

There is a strong inverse relation between the proportion of expenditure financed from retentions and bank credit.

Securities markets have declined in significance as source of finance for British industry. Trade credit increased in importance at the end of 1960s and early 1970s.

Small and medium sized firms are considerably more reliant on external finance than large firms. A smaller proportion of small than large company

- finance comes from securities market. Bank (and short-term) finance account for approximately two-thirds of UK companies total debt but more than five-sixth of small companies debt.
- 21 Demirgue-Kunt and Levine (1995) is the other significant study that collects and compares stock market development indicators in a cross-country perspective, from 1986 to 1993. This study's focus is on the characteristics of secondary market and relates them to financial development.
- 22 Singh is very circumspect on the implications of this findings. However, on their basis IFC seems to justify its efforts in promoting stock markets in these economies
- 23 This is estimated using CMIE (1994) and Datta Roy Chaudhury (1992).
- 24 These estimates are based on Datta Roy Chaudhury (1992) and National Accounts Statistic.
- These numbers should be interpreted cautiously. Private limited companies should not be simplistically viewed as 'independent' and/or 'small' firms doing better than large ones. As Hazari had revealed long ago, a sizeable proportion of private limited companies are closely related to large firms, in terms of ownership and management otien called 'satellite' companies in popular parlance Moreover, many holding companies that control India's large business houses are private limited companies Very often, newer entrepreneurial groups that emerge in capital market usually do so after their success with a number of private limited companies and family owned business
- 26 The average for the second half of 1980s is extended by a year to include 1990-91 as this marks an end of a certain policy regime. In this and subsequent graph, we avoid interpreting the trends since 1990-91, as the saving estimate is disputed
- 27 Interestingly, the period of rapid rise in the share of financial saving ratio is associated with rapid geographical expansion of banking services, though offered negative real interest rates
- 28 During 1989-90 and 1991-92, public sector tax-free bonds formed 40 per cent of capital market mobil.sation.
- 29 RBI's surveys of medium and large nonfinancial public limited companies, using uniform definitions and concepts since 1949, accounting for over four-fifths of private corporate sector's paid-up capital and sales forms the basis of this study

Using RBI company finance data, Datta Roy Chaudhury (1992), has arrived at 'population' estimates for the non-financial private corporate sector and relate them to national income aggregates. Thus we have consistent time series for about three decades since the mid-1950s

We also use RBI's flow of funds table for 'private corporate business'. This includes non-financial private corporate sector plus non-financial co-operative sector. Since the latter is very small, private corporate business can be proxied for the corporate sector.

- 30 These, we guess, are strictly comparable to Mayer's estimates as we use company balance sheet data, and on a 'net' basis.
- 31 Gross saving financed two-thirds of gross capital formation in private corporate business

- during the First Plan (1951-52 to 1955-56).

  The ratio came down to a little over one-third
- The ratio came down to a little over one-third in the Seventh Plan (1986-87 to 1987-88) [Ramachandra Rao 1989].
- 32 But, unlike then, when DFIs used to subscribe much of it as underwrites (as Goldsmith suggested), in 1980s public seems to hold bulk of the fresh equity.
- 33 Following Shanta's (1992) method, using Annual Survey of Industries, we estimate private corporate manufacturing value added by subtracting proprietary and partnership firms' share from that of 'wholly privately owned' firms.
- According to Goodhart (1992), "disintermediation is...said to occur when some intervention, usually by government agencies for purpose of controlling, or regulating, the growth of financial intermediaries, lessens their advantages in the provision of financial services, and drives financial transfers and business into other channels. In some cases the transfer of funds that otherwise would have gone through the books of financial intermediaries now pass directly from saver to borrower" (p 683)
- 35 We are very circumspect in interpreting this trend, since 1980s also witnessed an increase in competition in industrial goods markets in response to gradual loosening of investment licensing and import restrictions
- 36 This is a widely debated issue in recent literature developed country context. For a brief review of the literature and freshevidence for the US, see Samuel (1996b).
- 37 The Economist, (May 5, 1990) in a perceptively titled survey. 'Capitalism: In Triumph, In Flux', raised some of these issues, for a wider audience

Just in case you missed reading the May 7-21 issue, we thought we'll bring it your notice that the Business Today Survey rates us
No.1 among all Indian Banks.

At Corporation Bank, we believe good enough is not enough and it is reflected in our performance. As a pro-active, efficient, customer-oriented organisation, we've moved up from the 1993-94 position of No.3 to the No.1 position among all Indian banks in 1994-95. Thanks to our dedicated employees and to the unflinching loyalty of millions of customers, this marks the beginning of a new journey.

#### Too Little, in the Wrong Places?

## Mega City Programme and Efficiency and Equity in Indian Urbanisation

#### Sanjoy Chakravorty

The first major urban policy initiative announced after the government of India began the economic liberalisation process was the Mega City programme, directed by the ministry of urban affairs and employment. It is an attempt to shore up infrastructure in five of the six largest metropolitan regions in India (Bombay, Calcutta, Madras, Hyderabad and Bangalore), using innovative financing mechanisms, and emphasising cost recovery. After detailing the political-economic background, the programme and its implementation, three critical questions are considered one, is the amount of money being invested too little, and has it come too late to turn the situation around? Two, while programme being targeted to the wrong cities? And, three, will the elite continue to remain beneficiaries, and the moban poor neglected? The answers to these questions raise doubts about the Mega City programme. Since the reforms will have to succeed in the cities (if they are to be durable), urban development policies must be considered with a very to sustaining efficient and, specially, equitable urbanisation patterns.

WHEN the government of India announced a rapid economic liberalisation programme in July 1991, it joined a growing group of countries that have jettisoned development paths followed for decades for market orientation (Bokil 1990; Dehejia 1993). In the hubbub over exactly which industries should be opened to foreign capital and which protected, and how the new relationship with foreign capital should proceed, little attention has been given to spatial or urban development policy. This is surprising since the liberalisation programme will succeed or fail in India's cities. That is, the contribution of programmes for urban development to making the urbanisation process efficient and equitable may significantly impact the future of structural reform. The Mega City programme, which was initially announced in 1993, and is into partial implementation, is so far the only major urban policy component of the structural reform process. In the following pages I discuss the programme and its implementation. I argue that in the context of India's recent urbanisation pattern this programme may be inefficient because the wrong urban size class is targeted, and because the funds are not large enough to make a significant difference for the selected Mega Cities. Also, I argue that the role of the state should continue to focus on mitigating the effects of market failure and excess for the most vulnerable sections of the population; this is specially true when significant change, with the potential of further skewing the income distribution, is being introduced. As it is being implemented, the Mega City programme fails to address this concern, and appears to continue the centralisation and unequal distribution of resources. In the long run structural reform has to be politically acceptable (as the elite alone cannot keep it viable); this and other future

urban development programmes should be designed and implemented with social justice and political sustainability in mind.

The larger question raised here relates to the spatial dimensions of the post-reform development process. Indian policy-making has long been accused of lacking, even wishing away, all spatial aspects of development [see Johnson 1970; Lewis 1995]. In reality, every development action has a locational attribute which may affect the long-term prospect of the development action; a large literature in economic/ industrial geography deals with this aspect of development. In urban areas the central question has often revolved around the contradictions between the economies of agglomeration and scale on the one hand, and size-related congestion diseconomies on the other [Wheaton and Shishido 1981; Krugman 1995]. It is argued that for sustained, yet indeterminate, periods of time after the beginning of industrial development, large cities offer increasing returns to capital investment from higher labour productivity, larger plant size, and cost savings from proximate location of factors of production (suppliers, skilled labour, etc.) Eventually, though, the costs of size related congestion rise, and are manifested in higher wages and taxes, so that more efficient locations may be found in smaller urban areas. There is no agreement on what the optimal city size limit may be - the literature suggests that the efficiencies related to agglomeration may peak at urban sizes between three and seven million [Shukla 1984; Carlino 1985; Montgomery 1988]. Yet large cities often grow rapidly well beyond this size range. With reference to India, critics have pointed to 'urban bias' in macro-economic policy [Lipton 1977], or implicit spatial policies on transportation, import substitution, etc. as the source of this later growth.

Like all other development actions, structural reform, too, is not space neutral Markusen (1995) has argued that after liberalisation large cities may be favoured by large-scale industries, and hi-tech or innovative industries which need skilled labour, information and business services Export-oriented industries, on the other hand, may be able to locate in non-metropolitan settings (often in coastal locations). As a result we may see the creation of more dominant 'metroregions' or 'agglomerative fields' as in Sao Paulo in Brazil [Storper 1991; Diniz 1994]. That is, the reform process may result in further polarisation of population and economic activity into the already leading urban areas. This may be the efficient solution for industry (certainly when smaller urban areas lack basic infrastructure), but often is sub-optimal from a social welfare aspect: the costs of large city employment provision are high [Richardson 1987], interregional and intra-regional inequality may increase [Chakravorty 1994], and the problems of visible concentrated poverty, and metropolitan management become more acute.

The formulation or evaluation of urban/ spatial policy must be undertaken within this context. One must ask whether the existing large cities are efficient enough to offer agglomeration advantages, or some selected smaller urban centres may be better locations for new industry; one must know whether the investments to be made will be large enough, or sufficient to significantly improve productive potential. Once the questions on efficiency are answered, the policy-makers must deal with equity and evaluate the distributional aspects of the specific new policy (particularly as it is being implemented, rather than from a normative perspective), and in the context of the overall change in the policy framework

#### MEGA CITY PROGRAMME

Understandably, no new urban policy was announced immediately after the start of liberalisation. Neither did policy-makers act substantially on the report of the National Commission on Urbanisation (1988), which was the first comprehensive national level urban policy statement. The report was an urgent call to recognise the importance of urbanisation in the development process, and the policies necessary to make urbanisation manageable, sustainable, and equitable. The detailed and comprehensive report stressed the economic and social importance of the four largest metropolises (Bombay, Calcutta, Delhi, and Madras) and suggested that these be declared national cities with Rs 5 billion invested in each during the Eighth and Ninth Five-Year Plans. This investment recommendation has since been rejected by the policy-makers in the Planning Commission and the ministry of urban development (since reorganised into the ministry of urban affairs and employment, or MUAE), which felt that large-scale urban grants were incompatible with the new economic policy. Instead, in 1992, the MUAE and the Planning Commission initiated discussions on a new urban infrastructure financing scheme, called the Mega City programme (MCP).

The MUAE felt that the primary goals of urban development in the new economic order should be cost recovery and replicability of projects. Each project should be evaluated on its own merits - in terms of technical feasibility, revenue generation capability, etc - and should be financed as one item in a basket of feasible projects. Arguing that cost recovery was not possible in certain sectors, the MUAE proposed that three types of projects be put forward for the MCP: (1) no cost recovery (waste management, drainage and sanitation, etc); (2) partial cost recovery through user charges and taxes (water supply, transportation, slum shelter, etc); and (3) full cost recovery and surplus generation (housing, new area development, commercial complexes, etc). The suggested proportion of investment in these three project types was in the ratio of 30:30:40. The financial stake of the central government would be 25 per cent of the total programme cost, the state government would provide another 25 per cent of the cost; and the remaining 50 per cent would have to be raised from financial institutions such as HUDCO.

A Mega City programme outline highlighting these basic features was agreed upon in May 1993. On the basis of this outline the selected Mega Cities submitted their project lists over the following year (see next section). In March 1995 the MUAE clarified its position further, and specifically

underlined the following features: (1) Funds would not be provided for power, telecommunication, rolling stock such as buses, education, health, and small projects that could be implemented with local funds; (2) Only projects of regional or city wide significance, ones that are not of limited impact, and cannot be undertaken within existing municipality/agency budgets, would be considered; (3) A nodal agency, identified for each metropolis, would co-ordinate all projects and maintain a separate bank account in a commercial bank for all financial transactions under the scheme; (4) A sanctioning committee, with members from the central ministry, the Planning Commission, the state, the nodal agency, and financial institutions (for projects with institutional involvement), would examine and approve projects submitted by the implementing agencies, and review/monitor the implementation process; (5) At the end of the Ninth Plan period, a minimum of 75 per cent of the total outlay should remain available as an infrastructure development fund on a continuing basis [MUAE 1995].

The MCP is being implemented in five Mega Cities – Bombay, Calcutta, Madras, Hyderabad, and Bangalore. Originally the idea was to make the programme applicable only to agglomerations with populations more than five million in the 1991 Census. Hyderabad and Bangalore, both with populations between 4 and 4.5 million, were added later by the Planning Commission (after considering factors like estimated population in 2000, and urban growth rate). Delhi was not considered because its financing comes from a different account, the National Capital Region programme.

Project lists and outlines were prepared in response to the ministry circular from mid-1993 onwards. The nodal agencies responsible for these responses are: Bombay Metropolitan Region Development Authority (BMRDA), Calcutta Metropolitan Development Authority (CMDA), Madras Metropolitan Development Authority (MMDA),

Hyderabad Urban Development Authority (HUDA), and Karnataka Urban Infrastructure Development Finance Corporation (KUIFDC) for Bangalore. These reports were prepared before the more specific circular of March 1995 (discussed above), and as a result do not fully conform to its guidelines. For example, some nodal agencies have included additions to bus fleets among their costs; this will not be allowed according to the latest thinking. Also, an important element of the Mega City programme, the involvement of financial institutions with project specific cost recovery details, was generally poorly developed in these five project lists; i.e. these reports are similar to project reports that were done earlier - the MUAE wants new approaches in response to the new economic realities. As a result, according to the MUAE, these reports are not necessarily final - certainly not until the sanctioning committee for each Mega City has approved the 'basket of projects' [Mohanty 1995]. Nevertheless, these reports are indicative of investment priorities, and reflect a policy orientation that probably will eventually be implemented.

Table 1 lists the sectoral spending allocations planned within the Mega City programme for the five selected cities. It is clear that the spending priorities for the five metropolises are significantly different. Also, the amount planned for varies considerably from metropolis to metropolis – from a low of Rs 700 million for a single year in Bangalore, or a five-year low of Rs 1,698 million in Madras, to a high of Rs 6,080 million in Calcutta.<sup>2</sup>

In Bombay the projects are divided into two types – one for which there will be some degree of cost recovery through taxes, duties, user charges, tolls, etc, and the rest, which may be considered pure public investments. The projects with a cost recovery element include urban renewal, street lighting, bus service, water supply from Morbe dam, a diagnostic centre, and bridge tolls. Excluding Navi Mumbai Municipal Corporation (which

TABLE 1. MEGA CITY PROGRAMME INVESTMENT PLANNING

| Sector                   | Bombay | Calcutta | Madras | Hyderabad | Bangalore |
|--------------------------|--------|----------|--------|-----------|-----------|
| Transportation           | 37.8   | 17.7     | 19.0   | 20.6      | 71.4      |

| Slum improvement         | 0.5    | 1.8      | _      | 1.0       | 7.0       |
| Other                    | 5.4    | 2.9      | 5.4    | 4.1       | _         |
| Total (per cent)         | 100 0  | 100.0    | 100.0  | 100.0     | 100.0     |
| Amount                   | 4034   | 6080     | 1698   | 3985      | 700       |

Note: Figures shown are for percentage of total investment in each sector. The 'amount' is in million rupees. The data for Bombay, Calcutta, Madras, and Hyderabad are planned Mega City programme investments in the Eighth Plan (1992-97), The Bangalore data are for the financial year 1993-94 only.

Sources: BMRDA (1994); CMDA (1994); Kirloskar Consultants (1994), Government of Andhra Pradesh (1994); Government of Karnataka (1993). accounts for Rs 192 million of the budgeted total of Rs 4,034 million), 52.5 per cent of the total investment is to be spent on 'cost recovery' projects. Much of the cost recovery is to come from commercial development and transportation projects (though, interestingly, area development and housing do not figure prominently in the cost recovery list). Slum improvement is allocated less than 1 per cent [BMRDA 1994].

The CMDA in Calcutta has focused on area development/housing and commercial development as the cost recovery sectors. During the Eighth Plan the CMDA hopes to recover Rs 2,040 million in the area development/housing sector (from an investment of Rs 1,700 million), and Rs 1,095 million from commercial development (after investing Rs 990 million). The CMDA is clearly not expecting to apply user charges or tolls, since the combined cost recovery from these sectors is foreseen to be Rs 40 million (the investment being Rs 2,290 million). As in Bombay, the slum improvement sector is virtually ignored (with a mere 1.8 per cent of the budget) [See CMDA 1994].3

The Mega City plan in Madras was prepared by a private sector consulting firm rather than by the MMDA. The plan makes a distinction between 'remunerative' and 'service' projects, with 70.4 per cent of the total investment belonging in the former category. Remuneration is expected from bus/truck terminus/parking facilities, shopping-cum-office complexes, a large sewage renovation plant in Kodungaiyur, and some new town development. No money has been budgeted for improvements to water supply or slum areas [Kirloskar Consultants 1995].

The Hyderabad Mega City plan, appears to be heavily slanted towards the sanitation and water supply sectors (with over 61 per cent of the budget). Each HUDA project is classified as remunerative, cost recovery, or service most closely following the ministry guidelines – covering respectively 46 per cent, 25.9 per cent, and 28.1 per cent of the budget. Remuneration is expected from office, commercial, and shopping complexes, and water storage and supply; cost recovery is planned from sewerage improvements, hostels, and auditoria. Slum improvement is allocated 1 per cent of the budget [Government of Andhra Pradesh 1994].

The KUIDFC's response on behalf of Bangalore was unusual. Instead of proposing a five or 10 year investment plan (as the other Mega Cities had done), it offered a single year project list (for 1993-94). This list was worth Rs 700 million, much of it concerned with transportation (including synchronising traffic signals, improving street lighting and existing roads, creating an outer ring road, and purchasing 400 new

buses). About 7 per cent of the budget was to be spent on slum improvement through house construction and provision of basic amenities. The Bangalore report did not outline any cost recovery mechanism [Government of Karnataka 1993].

#### POLICY AND POPULATION BACKGROUND

The Mega City programme raises a number of issues, particularly since it is "being projected as the first post-liberalisation experiment by the ministry... "[Raina 1995]. Partly the issues raised relate to the question of efficiency - are the amounts being considered large enough to make significant changes, and whether these amounts would be better spent in smaller cities with more growth potential. Also, there are issues related to the liberalisation process itself - the argument may be made that the way in which the programme is designed and is being implemented, by ignoring equity considerations, may be counter-productive to the longterm success of market reform; in order to be durable, the reforms must receive support from populations other than the urban elite [Kohli 1989]. A summary of some relevant background information will help place a discussion of these issues in context.

First, consider the MCP in the context of other urban development programmes of the government of India, and the relative importance given to urban development in the national planning context. Table 2 charts the proportion of investment in urban development (often clubbed with housing) and for other major expenditure heads from 1961 through the Eighth Plan. The combined investment in housing and urban development, was less than 2 per cent until 1974, and has always remained below 3 per cent of total outlay. The urban development component has varied between 1.1 and 1.3 per cent from the Seventh Plan onwards. The

Eighth Plan came into effect after liberalisation, and reflects the changes in priority brought about by the New Economic Policy; investments in the financial years 1990-91 and 1991-92 were not part of any overall Five-Year Plan partly because of the impending shift to the new policy regime The difference between the Seventh and the Eighth Plans, should, as a result, reflect the new investment and policy priorities.

In general, though, using broad heads of development, there are few changes. The most significant change has taken place in the industry and minerals sector, whose share has declined by about 20 per cent; this follows declines of 32 and 13.5 per cent during the previous two Plan periods (the Fifth and Sixth Plans) - it can hardly be argued that a declining government interest in the ownership of heavy industry is a result of liberalisation. The share of the energy sector has increased by about 6 per cent, while that of transport and communication has increased by about 7.5 per cent. The last figure is somewhat misleading because the communications sector alone has seen an increase of about 50 per cent over the actual Seventh Plan expenditure. The social services sector of which urban development is one element, is now budgeted a 14 per cent increase over Seventh Plan actual spending (the bulk of the increase is in education). Clearly there has not been a fundamental shift in the policy-makers' attitudes towards urban development - it is receiving no special attention despite the clear argument that liberalisation will 'succeed' or 'fail' in India's urban areas (see conluding section).

The urban development sector money is mostly spent among the following programmes (1) Integrated development of small and medium towns (up to 5,00,000 population size); (2) Programme for the liberation of scavengers by conversion of

TABLE 2. INVESTMENT BY SECTOR (1961-97)

service privies into sanitary latrines; (3) Nehru Rojgar Yojana with programmes for urban micro enterprises, urban wage employment, housing and shelter upgradation, and training in trades with employment potential; (4) Urban basic services for the poor, aimed at ameliorating the living conditions of the most vulnerable urban poor; (5) Slum improvement scheme in non-metropolitan urban areas under the Minimum Needs Programme [see Dutt 1991 for a review]; and (6) Prime minister's integrated urban poverty alleviation programme (still being finalised) applicable to urban areas between 50,000 and 1,00,000 population size:

Second, consider the pattern of urban growth between 1971 and 1991. Table 3 lists the populations of the 23 metropolises with over one million population in 1991. The 1981-91 growth figures are illuminating.4 Among the poorest growth performers in the preceding decade are two of the five Mega Cities - Calcutta is ranked 20th, and Madras ranked 18th among the listed 23 cities. In listing the 10 fastest growing metropolises, we find only the Mega Cities Hyderabad (ranked third) and Bombay (ranked eighth). Bangalore, which has been much publicised as India's 'silicon valley', and 'air-conditioned city', and according to general opinion has been the country's exploding metropolis, ranks 12th. The 1971-81 growth figures are similar, Bangalore (third) and Delhi (eighth) are the only Mega Cities featured in the top ten.

Additionally, there appears to be a spatial/ regional dimension to the growth pattern. The southern state of Tamil Nadu has three of the four consistently slowest growing cities (Madras, Madurai, and Coimbatore). This may partly be a result of proximity to some of the faster growing urban regions such as Hyderabad, Visakhapatnam and Bangalore. There are only two eastern cities in the list - Calcutta has generally grown very slowly, and Patna, which was the fastest growing city in the 1971-81 period, became the slowest growing city in 1981-91. The northern cities show mixed results -- Kanpur has grown at a slow pace, whereas Delhi, Jaipur, and Lucknow have grown at widely fluctuating rates in the 1970s and 1980s. The western and central zone cities (especially Surat and Bhopal) have generally grown at a brisk pace.

#### THE QUESTIONS

Too little, too late?. In the Eighth Plan (1992-97) the amount budgeted for urban development, the source of the MCP funds, is Rs 52.77 billion. This money is to be divided among the programmes listed above, the National Capital Region Programme, and the MCP. In 1993-94 and 1994-95 the GOI released Rs 850 million and 840 million,

respectively, for the programme. Assuming that this will be the level of investment over five years, the total GOI stake in the MCP is likely to be in the neighborhood of Rs 4.25 billion (or just over 8 per cent of the urban development budget), though the official total Eighth Plan allotment for the MCP is apparently closer to Rs 7 billion (Raina 1995). Since this amount is envisaged to be a quarter of the total MCP investments, it is possible that between Rs 17 billion and Rs 28 billion would be invested in Mega City infrastructure through this programme by the end of the Eighth Plan. (The figures are likely to be significantly smaller now that three years have passed, and institutional borrowing has not been utilised.)

The significance of these figures may be better understood by comparing them to an estimate of infrastructure needs in one Mega City. In 1990 the CMDA calculated that during the 25-year period 1990-2015 the total infrastructure need for the Calcutta urbanised area was in the order of Rs 45 billion (in constant 1990 tupees). This figure includes a lower percentage of investment in the 'cost recovery' sectors = 9.5 per cent in housing and 11.5 per cent in commercial facilities (as opposed to the 28 and 16 per cent budgeted under the Mega City programme; see Table 1). Using conservative assumptions, the infrastructure need in Calcutta during the Eighth Plan is about Rs 10 billion; Rs 6 billion was budgeted in the MCP, of which perhaps Rs 3-4 billion will actually be spent. That is, there will be a shortfall of Rs 6-7 billion, in addition to the infrastructure deficiencies that have accumulated over the years

This situation would not have been remarkable had other sources of financing been available for all five Mega Cities After all, the GOI was under no obligation to create the MCP. The Mega Cities could have continued past practices - obtaining state funds (through octror and sales tax receipts, for instance), selling bonds, etc. These funds, however, are the source of the respective state's 25 per cent commitment component of the MCP. In most cases (Calcutta is an example) there is virtually no other money except some World Bank loans/grants.5 Clearly, the amounts being invested are too little to cope with the staggering needs of these Mega Cities, and have probably come too late to turn the situation around.

In the wrong places?. The wisdom of attempting to shore up crumbling infrastructure and fill the gaps in the Mega Cities alone is even more questionable in the context of the growth performance data in Table 3 Calcutta city and metro, Madras city and metro, and even Bombay old city now experience net out-migration to some degree, Calcutta and Madras cities have been facing massive net out-migration for over two decades now. These urban areas are probably all well beyond the point of net agglomeration benefits. The recent slowdown in the growth of Bangalore (which was taster than the national average in the 1980s, but much slower than its own pace in the 1970s) indicates that it, too, may be reaching the point where negative externalities and congestion diseconomies outweigh the agglomeration benefits. Hyderabad grew speciacularly during the 1980s, it is sure to slow down in the 1990s.

Sources Government of India (1993), Bose (1994)

These facts should be considered in the context of two others: one, the pace of urbanisation in India slowed in the 1980s (the urban population grew by 46.2 per cent in the 1970s, and by 36.5 per cent in the 1980s) [Bose 1994], and two, some non Mega Cities have generally outperformed even the faster growing Mega Cities. An argument can be made that the slow-down in Indian urbanisation is a result of saturation (and despite that, continued centralisation) in the Mega Cities." The MCP is a belated attempt to improve the carrying capacity of the largest metropolitan areas, where it is obvious that the second tier of cities is more likely to absorb larger shares of the urban population increment. The inefficiency and short-sightedness of the urban development policy orientation is further underlined when one considers the situation that cities with populations between a half million and four million receive few incentives from New Delhi. Most of the urban programmes discussed earlier do not apply to this size class; international financing also is generally unavailable for infrastructure improvements. The MCP funds, which are too small to effectively make a difference in the Mega Cities, could, on the other hand, substantially impact a selected set of the second tier cities.

For the wrong people?: Investment in slum improvement is conspicuously absent or relegated to an afterthought in the individual MCP spending plans. In Bombay, Calcutta, and Madras, 35 per cent of the metropolitan population lives in slums. In Bangalore and Hyderabad the corresponding figures are about 20 and 30 per cent respectively [all data are estimates for 1990; see Gupta 1993]. An infrastructure improvement plan that effectively ignores such large proportions of the population can charitably be described as blind. It is possible that the relevant authorities in these Mega Cities expect that international agencies, known for their tendency to financially support slum improvement programmes, will step in; and, direct poverty alleviation programmes like the existing Nehru Rojgar Yojana (NRY) programme, will suffice. (The other programmes listed earlier, with the exception of the programme for the liberation of scavengers, do not apply to the Mega City size class.) In the state of West Bengal, all urban areas (including Calcutta) received a total of about Rs 136 million for all urban development programmes (including NRY) in 1993-94; between 1990 and 1994 the NRY programme contributed Rs 230 million (of which the subsidy or grant component varies between 25 and 40 per cent) in urban West Bengal [Government of West Bengal 1995]. It is difficult to argue that this spending pattern is equitable.

Apart from the problem of inequitable spending or investment patterns, the larger

question relates to the income distribution impacts of a rapid liberalisation programme. On the one hand there is the argument that there is "no strong evidence to suggest that external liberalisation increases income inequalities in developing countries" [Harris 1995:175]. On the other hand an "obvious fear (and expectation) is that the poor and poorly represented, together with large sections of the organised working class, will be made to bear the cost of an imperfect and expensive package of reforms" [Corbridge 1991:473]. If Latin America and China's experience with structural reform is any guide, there can be little doubt that the sudden opening up of an economy will lead to increased income inequality [Khan 1993]. There is a rich literature on the subject of uneven development, the economic prospects of 'backward' regions in a market economy, and the impact of technological change on the distribution of income. [The work of Myrdal, Kuznets, Hirschman, Kaldor, Amin, Friedmann, Stohr and others is summarised and updated in Williamson 1991, and Chakravorty 1994]. This literature suggests that when development begins, or there is a significant change in the economic structure, certain cities, regions and people are in better position to take advantage of the new conditions; in the short run, at least, national and regional inequality is likely to increase [see Cohen 1990; Gilbert 1993].

Less is known about the intra-urban distribution of income in developing countries [except for Mohan's work on Colombia; see Mohan 1994]. In developed nations there is considerable evidence that inequality levels are higher in large cities due to unequal ownership of land and other productive assets, unequal skill distribution, differential migration, industry with entry barriers, etc [see Nord 1984; Chakravorty 1996]. These conditions are likely to be accentuated with rapid structural reform. Therefore, an argument may be made that the intra-urban distribution of income will become, and perhaps has become, more unequal as a result of economic liberalisation. This will happen at the same time that the national distribution of income becomes less progressive, and regional inequalities are exacerbated; the potential negative consequences of liberalisation for income distribution in general, and backward regions in India has been recognised by even the most ardent supporters of the process [World Bank 1989].

The MCP is a drop in the bucket of the Indian budge. It is, however, the only national urban programme of consequence for the largest size class, and one that is clearly designed as a prototype. One of the likely repercussions of the programme will be increased investment in the already relatively well endowed parts of the nation, the chosen Mega Cities, and their higher

income population groups. While this may, in some cases, increase their productive potential, the distributive impacts are clearly regressive. Perhaps the most important lesson of urban planning and development in the west is that it must promote social justice [Healy 1992]. Right now the general population appears to be sceptical of and resistant to liberalisation, while the business and professional elite are in support. In order for liberalisation to be successful, however, support must come from the economically weaker sections of society. Clearly many politicians realise the distributive significance of liberalisation - in recent assembly elections (in Andhra Pradesh, for instance) a major plank has been the promise of rice at Rs 2 per kg. In increasingly chauvinistic and parochial times, risking fairness for infrastructure may be a dangerous gamble.

#### SUMMARY EVALUATION

The MCP, small as it is in comparison to the size of the Indian budget and economy, is an important first step in Indian urban policy. In the federal structure of the Indian Constitution, urban development is a state subject. The maximum money previously invested by New Delhi on a city was Rs 1 billion in Bombay for the Indian National Congress centenary celebration. This new policy direction is expected to achieve a number of goals: force fiscal discipline and accountability by tying money to specific projects, and not letting the money disappear into labyrinthine municipal or development authority budgets; create a rolling fund which will be available for infrastructure improvements continually; collect user charges at rates close to the marginal cost of service provision.

By using a one-size-fits-all approach, however, the impact of the programme is likely to be diluted. Instead of using population size alone as the criterion for selecting cities for the programme, variations in the rate and spatial pattern of urbanisation should be considered. First, the regional aspects of urban growth, particularly in the south and east zones, should be considered. For instance, Madras, Bangalore, and Hyderabad cannot and should not be dealt with in the same manner - the historical and locational particularities should be taken into account. Second, if efficiency is the goal - that is, the purpose is to help create the bases of capital accumulation - a more appropriate strategy may be to foster the development of emerging metropolises like Pune, Surat, Lucknow, Vadodara, Cochin, Bhopal, and Vishakhapatnam.7 Not only would some equity purpose be served (by decentralising to relatively lagging regions), but the cost of future urbanisation and resultant infrastructure provision is also likely to be significantly lower.

Finally, cost recovery should be more carefully implemented. Cost recovery as a goal is unquestionably important and necessary, but the manner of proposed implementation is worrying indeed. First, in all the Mega Cities, the primary form of cost recovery appears to be through the delivery of area development and housing projects, and commercial development complexes. User charges and tolls are mentioned in some cases, but clearly these do not constitute either a majority or a significant fraction of the costs to be recovered. That is, faced with a new economic reality, the urban planning and development system in the Indian Mega Cities is responding by avoiding difficult choices. Instead of instituting realistic user charges for basic services (water supply, garbage removal, etc), and providing cross subsidies for the economically weaker population, the development authorities are preparing to intensify their participation in an economic sphere best left to the private market. The provision of high and medium income housing, and commercial centres is done most profitably and efficiently by private developers; public agencies are simply continuing to use their leverage in land acquisition (often the most difficult part of urban real estate development) to become major players in the land market. Perhaps the MUAE will disallow such practices; their list of typical projects, however, does specifically mention housing and commercial and area development.

The issue of cost recovery from basic infrastructure goes to the heart of the question of equity; subsidies always benefit those who are able to use the subsidised items. Water costs are subsidised by 60 to 80 per cent in the Mega Cities, at the same time that upper income groups use four to five times more water than slum dwellers on a per capita basis [Kundu 1994]. Middle and upper income groups pay about Rs 6 to 12 per person per month for potable water delivered to individual residences; a bottle of cola, one of first products to come in with liberalisation, costs about Rs 7. Surely it is not technically and politically infeasible to extract the marginal cost of water supply from these income groups, and continue the subsidies for the slum population (who do not, in general, have residential delivery systems). As the Mega City implementation plans stand now, cost recovery from the provision of services is really not a goal, if it was, the question of equity would not have been as important.

#### **PROSPECTS**

The impact of globalisation of trade and production and economic liberalisation in many developing economies is initially likely to be felt most directly in the giant cities of the lagging nations. These metropolises, and

not the smaller cities, have the necessary skilled labour and minimum infrastructure needed to attract footloose capital [Behrman and Rondinelli 1992], and more than ever before these metropolises have to be in open competition with each other (see Cook and Hulme 1988]. In India this situation appears to be recognised tacitly rather than openly. In the four post-liberalisation years, several state governments (including Haryana, Kerala, Orissa, Punjab, Rajasthan, Bihar, West Bengal, and Maharashtra) have instituted industrial policy reforms that are clearly geared to investments in the urban sector. Many states have lowered environmental hurdles, promised project clearance in hours if not days, and have sent their chief ministers abroad to solicit investments. The Mega City Programme appears to have been designed in a political-economic vacuum where these larger forces are absent. The questions that need addressing go beyond tinkering at the margins with urban infrastructure - these questions should relate to urban system structure and intraurban reconfiguration, the desirability and management of Mega City hypergrowth, the costs of Mega City urbanisation, the population carrying capacity of medium sized agglomerations, the interpersonal and spatial distribution of benefits, and poverty alleviation.

Finally, how will the success or failure of the MCP be evaluated? Surely it will not be measured by how it affects the rate of migration to the Mega Cities. Rather, if a revolving fund can be generated that may be used for the long-term sustenance of these cities, the policy-makers can justifiably claim some success. If, in the process, some cost recovery mechanisms (in the delivery of basic services) are instituted, there will be further reason for cheer. I do not believe, however, that the national rate of urbanisation will be considered a factor in the measurement of success, nor will equity issues in general. For a true social cost benefit analysis, the programme should be evaluated using these criteria. It is not enough to simply be marketoriented; it is just as important to be aware of market failures - which, in the Indian case, may involve both inefficient urbanisation and inequitable distribution patterns.

#### Notes

[The research for this paper was funded by a senior fellowship from the American Institute of Indian Studies, University of Chicago, and a summer fellowship from Temple University The author also wishes to thank the many individuals and institutions in New Delhi and Calcutta who have been generous with their time and resources.]

1 As of October 1995 the sanctioning committee had met for the first time in Bangalore, Bombay, and Madras, and some projects had been

- cleared The committees for Calcutta and Hyderabad had not me' yet
- 2 Note that the data shown in Table 1 are for the Eighth Plan period (1992-97), with the exception of Bangalore's single year plan. However, all the metros (but Bangalore) actually submitted spending plans running through the Ninth Plan (i.e., 2002), but I have elected not to show that data here, when the spending details spread over two plan periods are considered, the percentages allocated to the different sectors change, but not by large margins
- 3 This is particularly surprising in CPI(M) ruled Calcutta, more so because the most significant success of the CMDA has been in slum improvement (see Pugh 1989).
- 4 The growth figures in the following paragraphs should be considered in the context of India's overall population growth rate (23.9 per cent) and urban growth rate (36.5 per cent) in the decade 1981-91
- 5 In all five Mega Cities there currently are World Bank financed urban development projects – usually funds targeted to specific projects, particularly in the transportation and slum improvement sectors. In Calcutta the Bank aided CUDP-III ended officially in 1992, and has not been renewed, spillover projects are still being implemented.
- Within the Mega Cities themselves, the spatial pattern of investment is heavily skewed towards the older, most densely populated, overbuilt, slow growth central cities. In Calcutta it has been estimated that over 60 per cent of the MCP funds are targeted to the core city and its immediate surroundings. In Madras, the city corporation will get over 36 per cent of the funds directly (in addition to much of the investment by MMDA and Metro Water), while all other municipalities get less than 2 per cent combined In Bombay, where the old city actually lost population in the 1980s and Greater Bombay (smaller than Bombay inctropolis) grew by only 20 per cent, the spending plan is more balanced from a spatial perspective
- 7 The recent plague scare in Surat was a direct result of infrastructure and public health deficiencies in the face of massive population growth. These cities are growing rapidly without commensurate public investments, and could easily turn into 'dying cities' like Calcutta and Madras in two decades. It is unfortunate that even today the case for urban planning has to be made by raising the issue of public health, it is even more unfortunate that not a single programme to deal with the Surats has emerged, despite a narrowly averted disaster
